Army medical service in India, 495
Ascaris lumbricoides, 209
Assyrians, metrical system amongst the, 498
Asthma, on, 382, 401, 422, 440, 459
Asthma, iodide of potassium in treatment of, 157
Asylums, inebriate, 97
Athletic examinations for the army, competitive, 493
Atropine, a new source of, 205
Attar of roses, 205
Atthill, Dr. Lombe, injection of hot water into the uterus in cases of post-partum hæmorrhage, 26
Aural affections, some practical remarks on, 147
Auscultation, telephonic, 79, 126
Autopsy society, mutual, 432
Australian wines, 418

B

Bagot will case, the, 431
Barton, Dr. J. K., disease of hip, 190
Basal meningitis in children, localised, 330
Battle fields, disinfection of the, 265
Ballard's, Dr., report on effluvium nuisance, 220
Ball pessary retained in vagina for three years and a half, 484
Beach, Sir Michael Hicks, 137
Beamish, Dr., manual evolution successfully performed in arm presentation, 322
"Beautiful for ever," 182
Belfast Workhouse hospital, clinical instruction at, 37
Belladonna poisoning, 514
Bequests to medical charities, 121
Berkart, Dr. J. B., on asthma, 382, 401, 422, 440, 459
Bernard, Dr. Claude, 163; statue of, at Lyons, 514
Bethlem Hospital, the vacant superintendentship at, 371
Billroth, Dr., surgical pathology and therapeutics (Review), 434
Birmingham, sanitation in, 432
Bitters for beer, 78
Bladder, deformities of the, 106
Blatta on ulatis, 245
Blood-letting as a therapeutic, 455, 495
Blood letting in puerperal convulsions, 408
Blundell, Dr., the will of the late, 184
Boddy, Mr. Marlett, on the symptoms arising from the ascaris lumbricoides, 209
Borth fasting girl, 226
Bowel, deficient, 383
Bradley, Mr. S. M., on contractions, 519
Brain, functions of the, 215
"Brain," the new journal, 452
Bread for warriors, 79
Bright, Mr., on vaccination, 411
British Science Association, 59
Briton Medical Assurance, the, 355
Broadbent, Dr. W. H., acute dementia in a child, 105
Brougham, Lord, the centenary of, 513

C

Cabs, fever, 354
Cadaver alkaloids, 498
Cadier's laryngoscope (Illustrated), 445
Camphor, the therapeutics of, 55

Cairns, Lord, on homœopathy, 58, 80
Cancer Hospital, Brompton, 270
Cancer, remarkable cure of, 249
Carboniferous cephalopoda, 374
Carbuncle, treatment of, 393
Carmichael prizes, the, 143
Carpenter, Dr. Alfred, on alcoholic drinks, 399, 419, 439, 462; preventitive medicine (Review), 102
Casson, Mr. J. H., severe gunshot injury of elbow-joint, 212
Catalogue of the plants in the Society of Apothecaries' garden at Chelsea, 531
Centenarians, Irish, 370
Centenary of Lord Brougham, the, 513

OLD SERIES, VOL. LXXV. } No. 2,021. WEDNESDAY, JANUARY 9, 1878. { Price 5d. Post Free, 5½d.
NEW SERIES, VOL. XXIV. }

Fcap. 8vo, cloth, price 2s. 6d.

MATERIALISM. By J. M. WINN, M.D.
By the same Author, crown 8vo, limp cloth price 1s.
NATURE and TREATMENT of HEREDITARY DISEASE.

By the same Author, crown 8vo, limp cloth, price 1s.
PLAIN DIRECTIONS for DEALING WITH an INSANE PATIENT.

London: Hardwicke and Bogue, 192 Piccadilly.

Now ready, crown 8vo, price 5s.

INTRODUCTION to PRACTICAL HISTOLOGY.
By GEORGE THIN, M.D.

"No more valuable text-book for the student will be found, nor one containing a greater amount of useful information."—MEDICAL PRESS.

London: Baillière, Tindall, and Cox, King William Street, Strand.

Now ready, Third Edition, Enlarged, price 3s. 6d.
A GUIDE TO THE
EXAMINATIONS at the COLLEGE of SURGEONS
of ENGLAND for the DIPLOMAS of MEMBER and FELLOW.
By FREDERICK J. GANT, F.R.C.S.,
Surgeon to the Royal Free Hospital.

"In truth a most useful Guide to the Examinations, and as such we recommend it to future Candidates."—*Guy's Hospital Gazette*

London: Baillière, Tindall, and Cox, King William Street, Strand.

Now ready, Seventh Thousand, price 1s.
THE VEST-POCKET GRAY,
or ANATOMIST'S *VADE-MECUM.*
By C. H. LEONARD, M.D.

"By dint of a small though clear type, and the exclusion of all unnecessary words, a marvellous amount of information has been condensed into a remarkably small space. The work is one which will be found of the greatest value as a pocket companion."

London: Baillière, Tindall, and Cox, 20 King William Street, Strand.

Now ready, price 6s.
PRINCIPLES of THEORETICAL CHEMISTRY,
with special reference to the CONSTITUTION of CHEMICAL COMPOUNDS.
By IRA REMSON, M.D., Ph.D.,
Professor of Chemistry in the St. John's University, U.S.A.
London: Baillière Tindall, and Cox, King William Street, Strand.

Just published, 8vo, One Shilling.
ON THE EDUCATION AND
TRAINING OF THE FEEBLE IN MIND.
By J. LANGDON DOWN, M.D., F.R.C.P. Lond., Physician to, and Lecturer on Clinical Medicine at, the London Hospital, Physician to the Normansfield Training Institution, &c.

London: H. K. Lewis, 136 Gower Street.

Just published, Fourth Edition, price 3s.
TREATMENT OF SKIN DISEASES.
By ROBERT LIVEING, M.D., F.R.C.P.,
LECTURER ON DERMATOLOGY TO MIDDLESEX HOSP. MED. SCHOOL.

"It is the best compendium of cutaneous therapeutics that we know of, and its rapid success is thoroughly well merited."—DUBLIN MED. JOUR.

London: Longmans and Co.

THE STUDENT'S GUIDE TO

DENTAL ANATOMY AND SURGERY.

By HENRY SEWILL, M.R.C.S. and L.D.S.,

Dentist to the West London Hospital.

"Admirably clear and concise. Cannot fail to interest and instruct, not the student only, but the general practitioner."—*Med. Press and Circular.*

"Has the merit of being extremely compendious."—*Brit. Med. Jour*

"In every sense worthy of being termed "A Guide to Denta Anatomy and Surgery."—*Student's Journal.*

"Intended as a manual for students, and it appears to be a very good one."—*New York Med. Journal.*

London: J. and A. Churchill, New Burlington Street

Second Edition, considerably enlarged, price 5s.

ON FOOD: Its Chemical Composition, Nutritive Value, Adulterations, &c.

By HNRY LETHEBY, M.B., M.A., Ph.D., &c.,

Professor of Chemistry at London Hospital, Food Analyst and Medical Officer of Health to the City of London.

"The present edition of Dr. Letheby's Lectures is practically a new book, and we confidently predict for it an enormous sale."—*Medical Press and Circular.*

"Dr. Letheby treads with a sure step on the subject of dietaries as constructed for hospitals, prisons, workhouses, and lunatic asylums. —*The Lancet.*

London: Baillière, Tindall, and Cox, King William Street, Strand.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trade generally.

The scale of charges is as follows:—

Seven lines and under	£0 4 0
Per line afterwards	0 0 6
One quarter page	1 5 0
Half-page	2 10 0
One do.	5 0 0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page 357, last vol.*)

Case V.—*Syphilitic Melancholia — Dementia — Syphiloma of Right Hemisphere, involving Postero-parietal Lobule and first Occipital Convolution—Syphilitic Degeneration of Cerebral Vessels—Left Hemiplegia.*

M. B., æt. 38, admitted into the Central London Sick Asylum, Sept. 10, and died April 12, 1875. A woman of loose and intemperate habits, she contracted syphilis in the year 1870, and has suffered more or less from it ever since. Her friends stated that, for twelve months previous to her coming under my care, she complained greatly of pain in the head. At times she would be morose and depressed, then again excited, and almost unmanageable. On one occasion she attempted to commit suicide by jumping out of a window.

When I first saw her, the countenance was extremely typical of the mental state. Perception and volition were affected in equal ratio. She would sit gazing vacantly into space for hours together, and it was with difficulty that she could be roused to feed herself. She would not take food unless she was compelled, and she would remain like a living automaton, neither eating, drinking, nor taking notice of any one unless excited to do so. The countenance was heavy, the complexion muddy, the eyelids drooping, the eyes lustreless, the mouth partly open, with saliva dribbling from the corners; special senses apparently dulled; the optic discs were hazy, arteries small, veins large, the choroid injected and pigmentated. She walks co-ordinately, does not totter or falter, but locomotion is performed with slowness and apparent doubt of her own power. There is neither general local nor volitional tremor, and it must be remembered that ideation is almost lost. Articulation is perfect, as far as it goes. There is marked decrease both of muscular and cutaneous sensibility, but no objective paralysis of cranial or spinal nerves. Now and again she seems insensible to the involuntary discharge both of urine and fæces. Urine, gr. 1,010, high coloured, loaded with lithates, but free from albumen. Pulse regular, with slightly increased tension. Temperature usually below the normal. Her condition progressed unfavourably. About two months before her death I noticed that she was partially hemiplegic upon the *left* side of the body, more of the leg than of the arm, and more of motion than of sensation. The paralysis increased, until it became complete, with fixed contraction of both the arm and leg; and what was rather remarkable, though not unusual, about a fortnight before she died, her brain became much more perceptive, and a dawn of reasoning power evidenced itself. It was only transitory, and of short duration, for she gradually sank, becoming more obtuse day by day.

The *post-mortem* examination showed the condition of the brain to be as follows:—The internal surface of the cranium was free from any morbid change, and also the dura mater. The sinuses were more or less engorged with blood. In connection with the arachnoid and pia mater was a morbid growth, which extended deeply into the brain substance of the postero-parietal lobule and first occipital convolution of the right hemisphere, giving rise to considerable adjacent softening, hæmorrhage, and blood. staining.

The whole of the right centrum ovale was hypervascular, and studded with small bleeding points when cut through. The right corpus striatum was also discoloured, and softened in patches. The left hemisphere was of normal appearance and consistence. The convolutions over both hemispheres were shrunken, but particularly those of the *right*. There was also an appreciable difference between the grey matter, which was softer and more hypervascular in the convolutions of the latter than of the former.

Under the microscope the grey matter of the right convolutional surfaces was remarkable for the large number of vessels brought into view, to the exclusion of the normal

cellular elements. The latter had undergone considerable atrophic change, and were, in a measure, replaced by a hyperplasia of connective tissue corpuscles.

As to the vessels, they were diseased, and gave the characteristic appearances usual to such condition—viz., dilatation, waviness, and irregularity of outline, thickening, destruction, and separation of the tunics, which were seen to be crowded by a multiplication of small nucleated corpuscles, and perivascular spaces existed.

It would have been of some interest to have noticed the cellular degeneration in the several layers of the grey matter, but in this case it was forgotten; and I do not think it is of so much importance as in some other forms of cerebral degeneration, which will be noted further on, especially in the general paralysis of the insane, where it becomes a point of the highest significance, and one which hitherto has not received such an amount of investigation as the subject deserves. Up to the present time we are more indebted to the researches of Drs. Herbert Major, Batty, Tuke, and Ringrose Atkins than to any other observers in this country.

I cannot, for my own part, see any reason whatever to doubt the purely syphilitic origin of the disease which existed in the brain of this woman. Although of intemperate habits, she was healthy, until syphilis commenced its destructive work. In my opinion, if she had not been a drunkard, she would not have had the diffuse change in the structure of the brain, and possibly the gummatous mass would not have had an existence.

A careful examination of the viscera showed sclerosis, but uothing more. There were pleuritic adhesions. The heart was normal in size, but rather flabby; valves healthy; liver contracted and hardened; spleen the same; kidneys small, contracted, and granular.

CASE VI.—*Syphilomatous Growth of Tentorium Cerebelli and of the Sinuses entering into the Formation of the Torcular Herophili—No marked objective Paralysis.*

This case is of unusual interest, pathologically, physiologically, and clinically, and, so far as I can ascertain, no similar condition has been recorded.

W. W., æt. 39, was admitted into the Central London Sick Asylum on Nov. 16, 1874, and died Nov. 1, 1875 He contracted syphilis when a young man, but suffered little from it at the time. For many years the state of his health had been indifferent, and for the past eighteen months he has been unable to follow any occupation. There is no history of fits. It appears that he was compelled to give up work on account of the severe shooting pains affecting the skull, but more particularly the frontal bones. At this time his sight began to fail, and when he attempted to read, the letters looked double; straight lines appeared to be curved, and ran into each other. The smell, also, was impaired, and offensive matter made its way from the nostrils. The power of locomotion was interfered with from sensoro-volitional derangement; he felt confused, and stopped short from attacks of *petit mal*, and would reel and fall unless supported. The bowels were obstinately confined, and he vomited after nearly every meal. In addition, he suffered from otalgia, with intermittent otorrhœa. When I first saw him, the above signs and symptoms were well marked. He was pale, and over the right frontal eminence was a cicatrix, the result of previous ulceration, which had given exit to some necrosed bone, and prevented the movement of the occipito-frontalis muscle on this side, and gave one the idea that the supra-orbital and facial nerves might have been centrally affected. But this was not the case. The ophthalmoscope showed a hazy outline of the optic discs, the veins were exceedingly large, and the arteries small; in fact, there existed a neuro-retinitis, going on to atrophy. *There was no objective paralysis of cranial or spinal nerves.*

The special senses of smell, sight, and hearing were impaired from localised disease in these organs. Cutaneous sensation and sensibility were everywhere normal, and the muscles responded readily to the galvanic current. The sphincters were unaffected. There were no formications, no tremor, and no automatic or reflex convulsive movements. He complained of the head feeling heavy, so that at times he was unable to raise it from the pillow. But one of the especial features of the case was the association of signs and symptoms, such as cessation of discharge from the ear, followed by intense headache, persistent vomiting, and obstinate constipation. These attacks were paroxysmal, and lasted for eight or ten days. At other times he was tolerably well. The intellect was rarely affected, but the memory was variable. The pulse, temperature, and respirations were normal. He died after a prolonged attack of persistent vomiting. These attacks came on with the slightest movement of the head as well as after taking nourishment. There was also bilateral rigid spasm of the muscles of the neck.

Post-mortem examination. (*a*)—The cranium was unusually thick, compact, and heavy; its outer surface was covered with nodular elevations; the inner surface was free from any outgrowths. The dura mater was easily reflected from the surface of the anterior lobes, but it was almost impossible to remove the posterior part of the falx cerebri where it was continuous with the tentorium, and bound down to it by an adventitious growth. There were strong adhesions between the latter and the cerebellar and occipital lobes, but more particularly between the upper surface of the lateral lobes of the cerebellum and the under surface of the post convolutions of the parietal lobes. In addition to this, the growth had invaded and secluded all the sinuses in relation with the torcular herophili, except the two occipital. It had also invaded the whole of the tentorium cerebelli, but more on the left than on the right side. It presented the same appearances throughout, had a yellowish colour, was of firm and elastic texture, and under the microscope it was seen to be made up of wavy, connective tissue infiltrated with round cellular elements.

When one considers the apparently serious nature of the seclusion of the large sinuses, it seems wonderful that the cerebral circulation was not more objectively interfered with; yet, as we have seen, there was not one single iota of evidence in proof of this important impediment to the return of the venous blood to the right side of the heart; neither do I think that we should have had any of the attendant phenomena, as vomiting and *petit mal*, were it not that the cerebellum was involved.

There were no very objective signs, however, of cerebellar disease. For instance, there was no inco-ordination of the muscles of the eyeballs, oscillation, or nystagmus, but there was evident want of balancing power, or ability to maintain the equilibrium. I think negative signs like those in this case indicate much in cerebral physiology—viz, that certain parts of the brain must be involved, in order to obtain definite effects. This is of great moment, and does more, perhaps, to clear up abstruse points as to what are the motor functional centres of the brain than direct experiment upon definite convolutions.

In this case, for instance, none of the centres for direct volitional movements were diseased; hence we found that during life we had no motor paralysis beyond the want of co-ordination in the muscles of the lower limbs from the direct injury to the cerebellum.

(To be continued.)

ACCOUNTS of the first week in December state that small-pox is ravaging the city of Algiers and its suburbs. The mean of the deaths has been 20 to 25 a day, especially amongst the Arab population inhabiting the frontiers. Foreigners are leaving the place, and the municipality has taken steps to prepare a lazarette for the small-pox patients, which is to be situated about four miles from the town.

(*a*) Shown at Pathological Society of London, Nov. 16, 1875, and then forwarded to the College of Surgeons and Physicians.

A FORM OF PARALYSIS SYMPTOMATIC OF LESION OF THE PONS VARORLII. (a)

By Dr. SIGERSON, F.L.S.

THE term "alternate paralysis," originally given by Professor Gubler, was preferred to the mis-translation, "cross paralysis," sometimes employed, because the former indicated not only that the effects were manifested on opposite sides of the body, but also that the lesion operated at different relative heights on the nerve centre.

Tracing the history of the disease, Yelloby was mentioned as the first, in 1808, to record a case; from which, however, he drew wrong conclusions. Then came the case of Dr. Vieusseux, of Geneva, which had been entitled, "a singular nervous or paralytic affection." These two cases might serve as types, the first, of *alternate motor-paralysis*, which Professor Gubler had described; and the second, of *alternate sensory paralysis*, to which Dr. Sigerson directed attention. There was a third form, *alternate mixed paralysis*, of which he would give an example in concluding. Illustrative cases, more or less free from complications, were noticed in the works of Salter, Abercrombie, Bright, and Cruveilhier—the latter of whom had frankly acknowledged that he knew no characteristic sign for apoplexy of the pons. Dr. Annan, of Baltimore, U.S., related in 1841 the incidents of a case in which sensory and motor paralyses affected the same region, and added some observations which showed that the logic of the physician may sometimes precede the scalpel of the anatomist in the elucidation of obscure points of structure. Lockhart Clarke's remarkable researches had since set all doubt at rest, and made science advance with rapid strides.

It was next shown that the third or mixed form was subdivisible into two kinds (*a*) *coincident* alternate paralysis, where, as in Annan's case, paralysis of motility and sensation coincide; and (*b*) *sensory-motor* alternate paralysis, where they cross like the stroke of an X. Longet had quoted a case from Carré, but Romberg appeared to have been the first (1842) to diagnose lesion of the pons, in a case of alternate paralysis, before the autopsy.

A new epoch in the history of the disease, was made by Professor Gubler, who, in 1856, published his earliest investigations, and gave this symptomatic group its present name. His view was contested by Trousseau, on the authority of a case which Dr. Sigerson concurred with Dr. Gubler in believing had been misinterpreted. The opposition fortunately gave rise to wider and deeper research, and in 1859 Professor Gubler having collected and collated all the cases recorded in France, published a record memoir, in which he might be said to have legislated for the disease with considerable, if not complete, success. As his work was not known in these countries, except through the pages of Trousseau, although he first had brought the disease fully into light, an analysis of his views, and a summary of his conclusions were given. It was shown that, exceptionally and rarely alternate paralysis might be produced by lesions not pontine, but peripheral, cerebro-peripheral, or perhaps, purely cerebral. Dr. Benson, of Dublin, could claim priority in recording a case of the first kind; this was described, and other examples were given. For these the designation, *mimetic alternate paralysis*, was now proposed.

Professor Gubler had candidly confessed that diagnosis in the case mentioned would have been impossible; but Dr. Sigerson explained that this impossibility no longer existed; and that a differential diagnosis can now be made by the method of electro-muscular exploration, which is due to his regretted friend and master, Dr. Duchenne, of Boulogne. Having described the several kinds of true alternate paralyses (including alternate hemiplegias), and Professor Gubler's division of the pons variolii into regions, he mentioned Dr. Brown-Sèquard's memorable articles and lectures, and then proceeded to deal with the question of differential diagnosis. He showed that some symptoms which had been relied upon as characteristic of peripheral, in opposition to cerebral lesion, were not to be absolutely depended on. Thus, with respect to paralysis of the orbicularis palpebrarum (which Récamier had first noted, and Todd described as "a pathognomonic sign" of a non-cerebral lesion), Dr. Duplay had given cases where this paralysis had been found in the aged, co-related to a cerebral lesion. Dr. Sigerson had himself had a case of right hemiplegia, when the patient was unable to close the right eye, when the indications, confirmed by electro-diagnosis, pointed to central and non-peripheral lesion. Facial paralysis, again, might be symptomatic of (*a*) brain lesion, or (*b*) of lesion of the superior pedinocular-pontine region; or (*c*) of the inferior or bulbar-pontine region; or (*d*) of the facial nerve at its point of emergence; or (*e*) of the same nerve in its course. The means of discriminating between these were noticed, and Dr. Sigerson pointed out how, in doubtful cases, electro-muscular exploration might be used to determine, say, whether a man were the victim of opium poisoning, or of pontine hæmorrhage. Grave errors had been committed in some instances from the difficulty of diagnosis in such cases.

With a view to determine the general features of the disease, he had collected and collated all the cases accessible in the home and foreign records, and tabulated the symptoms. These were then described in order, and it was shown that, with some exceptions, absolute signs were rare. Even paralysis of the sixth nerve, which Dr. Brown-Séquard had said "never exists except with disease of the pons varolii," might occur, especially in venereal cases, owing to pressure on the nerve in its course. Then, again, it might be indicative of something quite different from pontine paralysis, *i.e.*, of locomotor ataxia. Diplopia and strabismus, as Dr. Duchenne, of Boulogne, had remarked, might at the outset of the latter disease, stand almost, though not altogether, alone. He had, indeed, in his latter years, Dr. Sigerson said, contemplated omitting the adjective "locomotor." The questions of temperature, change, and nature and position of lesions were then discussed, and amongst the predisposing causes enumerated, might, perhaps, be mentioned the Celtic constitution, which, if any inference could be drawn from the records beyond a probable conjecture, seemed more liable to pontine affections than others, just as the so-called Anglo-Saxon race was, according to authorities, more subject than the Celtic to paralysis agitans.

The necessity of watching premonitory symptoms, and the advantage of a preventive treatment, having been dwelt upon, Professor Gubler's classification of the various kinds of alternate paralyses, known to him in 1858, was given. It did not, however, include all the species at present known. For purposes of reference, where a short descriptive title might be useful, Dr. Sigerson suggested the following classifications:—

Simple alternate paralysis (motor or sensory); *bend-dexter paralysis* (right face and left extremities affected); *bend-sinister paralysis* (left face and right extremities affected).

Coincident alternate paralysis (sensory and motor paralyses affecting same regions).

Double alternate paralyses. Complete *X-shaped paralysis* (both sides of face and extremities of both sides of the body affected).

Incomplete *X-shaped paralysis* (both sides of face affected).

Y-shaped paralysis (both sides of face, and the extremities of one side of the body affected).

λ (lambda)-*shaped paralysis* (one side of face, and extremities of both sides of the body more or less affected).

The terms "motor," "sensory," or "sensory motor," being added when necessary, a short title can thus be

(a) Abstract of a paper read before the Dublin Medical Society. The discussion will be found at page 4.

obtained, which may be serviceable. As cerebral hemiplegia is stated to be most common on the left side, the author had sought to ascertain whether any similar rule held good here; but he had found that, curiously enough, the balance was nearly even. There was a little predominance of what—borrowing a term from heraldry—he had called *bend-dexter paralysis*, but it was very slight.

Dr. Sigerson then described in detail, a case of "sensory motor Y-shaped paralysis," in which there were motor paralysis of the left side of the face, paralysis of sensation of part of the right side of the face, ear, arm, and right side of the body. There was decrease of dynamic strength, loss of heat, sense, formication, and trophic disorders in the right upper extremity. Internal strabismus and paralysis of the left orbicularis existed. The patient was treated by counter-irritation, the exhibition of medicines, and the application of faradisation, according to the practice of, and with the precautions habitually adopted by, Dr. Duchenne, of Boulogne. To this treatment the anæsthesia gave way, the deafness complained of in the right ear was got rid of, the facial paralysis improved, so that the power of incitation was recovered. The grasping strength of the right hand, as tested by the dynamometer, increased from 79 lbs. to 126 lbs., whilst the nervous incitation had notably augmented.

Having discussed various diagnostic symptoms, Dr. Sigerson concluded by directing attention to several inferences of pathological and physiological interest.

Transactions of Societies.

DUBLIN MEDICAL SOCIETY.

The second meeting of the session was held on Wednesday, December 5, 1877.

Dr. Gordon, President, in the chair.

Dr. Sigerson read a paper on

ALTERNATE PARALYSIS,

which will be found at page 3.

Dr. M'Swiney ventured to say that the paper they had just heard read belonged to a class of communications which it would be very desirable to have more frequently submitted to the members of the Society. The paper of Dr. Sigerson, dealing, as it did, with obscure lesions of the nervous system, must, to those engaged in active practice, be regarded as a great acquisition. Physicians knew that it very frequently occurred that, notwithstanding the most perfect diagnostic skill in regard of ordinary maladies, they often found that cerebral affections baffled investigation, and they knew how frequently the *post-mortem* examination failed to reveal the precise nature and extent of lesions which they had, during life, been led to expect existed. The investigations of Charcot, Ferrier, Hughlings Jackson, and others had served to point out the perfect state of chaos existing in regard to cerebral physiology and pathology. The memorable lectures delivered in Dublin by Browne-Séquard were more remarkable for one feature than anything most of his audience had listened to. In those lectures the able and celebrated physiologist employed himself in demolishing ruthlessly the entire structure which had been laboriously erected by previous investigators in cerebral pathology. Dr. Browne-Séquard gave abundant reasons for at least fearing that the basis upon which those investigations and deductions had been built was an unstable, an uncertain, and an unwarranted one. He, however, did not add to that destructive work of his—the work as yet of construction; and those who were in the habit of attaching importance to the views of the distinguished physiologist were now in the position of waiting for the new view which it would be correct to take regarding that subject—the ancient views which he had so mercilessly dissipated and destroyed. It must be satisfactory to find an affection such as that which the author of the paper had brought under their notice this evening, rendered by his labours more easy of recognition. Dr. Sigerson had shown them the means whereby, if they closely followed them, they might be enabled to more frequently and with more certainty detect the nature of particular lesions present in the various forms of alternate paralysis to which he had called their attention. For that, he (Dr. M'Swiney) was sure every practising physician — more especially those whose avocations and pursuits did not enable them to study the minuter diagnostic signs of those obscure affections—must feel grateful. He felt, of course, that the subject so elaborately treated by the essayist was too extensive a one to be minutely criticised. He fancied the communication was one that they must read in their studies, and ponder over with more advantage than they could derive by attempting to criticise or deal with it at present.

Dr. Henry Kennedy regretted he was unable to add anything to the exhaustive paper they had just heard. The truth was, cases like those detailed by the author were very rare. On only two points would he speak. The first was that the difference in temperature between the two sides of the body, alluded to by the author, was not due solely to disease in or about the pons. Dr. Kennedy had noted cases where the same difference occurred, and yet where the mischief was entirely confined to the corpus striatum and optic thalamus; and in one case brought before the Pathological Society during the past spring the difference of the temperature on the weak side was constantly 1½ or 2 degrees below that of the opposite or healthy side, as ascertained by Mr. Wilson, his clinical clerk. On *post-mortem* examination of this case, the disease, which proved to be a large tumour of the nature of glioma, was situated in the roof of the ventricle. The second point he would notice was the interesting case last given by the author, in which he thought it very possible that gout was the origin of the symptoms detailed. In many cases this poison gives rise to very anomalous symptoms of cerebral disease, and it may even happen that they will disappear on the occurrence of gout in the extremities. Dr. Lynch, of Loughrea, had published a series of cases of this kind, which were well worth reading. He would wish to know the present state of the patient, and whether any of the symptoms, which had been so well described, had in any way altered or disappeared.

Dr. Sigerson, in the course of his reply, said he was anxious not to detain the Society at any length. With regard to the question of the co-relation between the lesions and the temperature, to which Dr. Kennedy called attention, that was a subject upon which he (Dr. Sigerson) had avoided entering. It had been opened up by a quotation from Browne-Séquard; but beyond giving the quotation, he had not data sufficient to enable him to proceed further, neither could he give any opinion upon the probability of gout being a predisposing cause. He had very carefully tabulated all the causes alleged in the cases recorded in the home and foreign papers, but he did not find gout mentioned amongst any of them; therefore he could not enter it upon his notes, though he admitted, on Dr. Kennedy's experience, that gout might be inculpated here, yet, from all the precautions he (Dr. Sigerson) had taken, he was as certain as he could be that the lesion was in the pons varoli. He was almost as certain as possible that the lesion was a blood clot. It was possible that gout might have helped to get up a lesion of this form. In conclusion, he thanked the Society for the kind manner in which his paper had been received.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
AND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM.

Chapter VI.—Incubation, Frequency of Transmission, and other Kindred Subjects.

(*Continued.*)

The Theories on Incubation.

The virus being introduced through the skin, or through any abraded surface, the natural questions suggest themselves: Does it remain hermetically locked up for a time?

Does it produce a change in the system before the development of the symptoms? Is it a slumbering germ which may be roused into action by various exciting causes?

We have settled the fact of how rabies is caused, and we have arrived at tolerably definite ideas as to the period it takes before revealing its fatal effects; and we must now unfortunately enter the region of hypothesis, and see if we cannot arrive at some satisfactory explanation. We need not give the theories of very old writers, though they are interesting and instructive, and afford ample illustration, of how difficult it is to evolve a new idea. An endless field for speculation is opened out, and we must limit our selection of the theories advanced.

Faber imagined the contagious principle became encysted on its introduction, and that it entered the blood under the influence of certain favourable conditions.

Brown Séquard is of opinion that an alteration takes place in the part of the body bitten by a rabid animal, before the characteristic phenomena of rabies appeared; that the convulsions follow a kind of *aura* starting from the wound or cicatrix. He therefore lays the *locus in quo* in the wounded nerves.

This theory is negatived by the facts that the nerves have been excised, and the limb amputated without results, after the symptoms have appeared, also by the fact that in the majority of cases, the wounded part shows no evidence of alteration.

Zinthos and Marochetti suggested that the virus was first localised, and subsequently within a period varying from the 2nd to 28th day, was absorbed, and formed secondary "lyssi," consisting of a pustule or vesicle beneath the tongue.

Magistel says he saw these lyssi in different individuals on the 6th, 11th, and 20th day.

Marochetti asserted that these pustules were pathognomonic; that the virus accumulates, and is temporarily retained about the orifices of the sublingual ducts, on the sides of the frænum of the tongue, and on the lower aspect of that organ. In these places, several ephemeral pustules show themselves, whose fluctuation can be perceived by means of a probe. The time at which they appear is not certain, but they usually correspond to the interval between the third and ninth day after the bite, though they have been seen so late as the thirty-fourth day. If the virus in these pustules is not destroyed within twenty-four hours after they appear, it is re-absorbed, and the disease soon manifests itself. It is therefore necessary during six weeks, at least, to examine carefully, several times each day, the lower part of the tongue of a person who has been bitten (*a*)

If the pustules appear, open and cauterise them promptly; but if they do not form, it is certain that the individual will not suffer from hydrophobia.

Trousseau believed in the possibility of their appearance.

Romberg considered them a hoax, practised by a Ukraine peasant; the majority of observers have not discovered them.

We mentioned on a former occasion, a theory suggested in the *Lancet*, of 1827, under the name of "Mysotoxicos,' which offers a reasonable explanation of part of the phenomena. That the poison is localised for a time, we know from the result of excision.

Jesse Foote (*b*), in 1788, published a very valuable pamphlet, on the value of excision, dedicated to Pott. He reasoned from analogy, from the bite of a viper, and from experiments made on the guinea-pig, that excision would be useful before absorption had commenced. He also drew his inferences from the experiments of the Abbé Fontana, who had made 6,000 experiments on the effects of the bites of vipers.

We shall have occasion when dealing with preservative measures to return to Jesse Foot again.

(*a*) "Aperçu Historique sur les Lysses." *Recueil de Med. Veter.*, vol v., p. 658. Fleming, "Rabies and Hydrophobia" p. 169.

(*b*) "An Essay on the Bite of a Mad Dog," by Jesse Foot, Surgeon, Lond., 1788.

Dr. Anthony Todd Thompson (*a*) in his comments upon a case of rabies from the bite of a cat, in 1826, threw out the hypothesis that the virus remains dormant in the part where it is deposited by the tooth of the rabid animal, until a certain state of habit rendered the nerves in its vicinity susceptible of its influence, and this being communicated, a morbid action is begun in these nerves, and extended to the respiratory nerves, which induce the whole train of symptoms constituting the disease.

Mysotoxicos (*b*) tells us that everything leads to the belief that the virus, which has afterwards to contaminate the circulation, is generated in the wounded part from the germ first deposited there by the tooth of the dog, just as we see take place in variola, vaccinia, and syphilis, the period of assimilation being different in all these. But as soon as absorption of this assimilated matter commences, the symptoms of the disease begin to show themselves. He also says that modern and well authenticated experiments have proved that when a poison, whether mineral, vegetable, or animal, is applied to a wound, the animal is not affected until absorption has taken place, for if an exhaustive cupping glass be placed over the poisoned part, but one minute before the expiration of the time at which the poison is known invariably to produce its effects, the animal exhibits no symptoms whatever. The experiments of Jesse Foote (*c*) prove that a guinea-pig might be bitten by a viper, and five minutes allowed to elapse before amputation of the part bitten was effected, when the animal survived.

Mysotoxicos (*d*) also suggested, under the presumptive impression that in rabies, as well as in all other varieties of poisoning, the transport of the deleterious matter from the wound into the system, and the appearance of the symptoms followed, as cause and effect, some special precautions might be taken, even when the symptoms were pronounced.

When the cicatrix begins to feel at all tender, he advises:—

1. The immediate application of a cupping-glass for an hour.
2. The dissection out of the bitten part.
3. The re-application of the cupping-glass for another hour.

Whoever this writer may be, who fifty years ago adopted this pseudonym, and whose individuality is just as much lost as that of Junius, his views are rational; and though we cannot endorse them in full, yet they present as satisfactory an hypothesis as we can expect on part of the phenomena. They somewhat resemble the views of Todd Thompson, which have been revived by some modern writers, as Sir Thomas Watson.

The wound in the majority of cases does not asssume any inflammatory action, nor can we, by the naked eye, discover any alteration in the appearance, at the time of the development of rabies.

The action of the virus seems most to resemble that of syphilis, in which we have a period of latent action a period of absorption by the lymphatics, and a subsequent incubatory period of syphilisation. Further research is necessary, and experiments with the virus, as dissecting or excising the bitten part, and introducing it into some animal, and then watching its effects day by day.

Now that *bacteria* play such an important part in disease, we shall expect some results in this direction, and a further explanation of the remaining part of the phenomena.

Virchow, we know, was of opinion that the contagium of rabies has an action similar to that of ferments (*e*); that

(*a*) "Medico Chir. Transactions," vol. xiii., 1826.
(*b*) *Lancet*, vol. ii, p. 809, 1827.
(*c*) Jesse Foot. *Loc. cit.*
(*d*) *Lancet*, 1827. *Loc. cit.*
(*e*) This view is a return, to a certain extent, to an old theory. Etmullerus, in 1683, said: "The cause of this disease consists in a certain peculiar ferment, which affects first the spirits and then the blood. This ferment is carried along with the saliva into the wound."

the new elements introduced at the point of inoculation are being continually introduced into the blood, by means of which they act on the nervous system ; and that rabies only appears when these elements have accumulated in an excessive quantity (*a*)

As Fleming says there may be a double zymosis, first in the part, and afterwards in the system, the result of which is either to multiply the poison, or to increase its virulency.

There are many other ingenious speculations, as for instance, whether the virus is present in the secretion of the generative organs. For man we may answer by the following statements :—

Chabert relates that a female, the wife of the executioner, contracted the disease. She had cohabited with her husband up to the evening of his being attacked with rabies, due to his having been bitten by a rabid dog.

Hoffman relates a similar case ; but Bandot mentions the case of a young woman who had cohabited with a soldier for a month, from the day when he had been bitten by a mad dog, until rabies manifested itself, without becoming affected.

Bouteille, Boissiere, and Rivollier, mention cases in which sexual intercourse took place within only six hours of the appearance of rabies, without transmission.

We may dismiss this idea as only a speculation for the curious, and negative the possibility of infection by any such source.

We may summarise then, our knowledge of the theory of incubation.

The smallest quantity of the virus is potent, and being introduced, *probably* remains localised for a period, and *probably* zymosis explains the subsequent action. This action may be excited by many internal or external influences, as excitement, anger, fear, injury to the cicatrix, &c.

Frequency of Transmission.

As we have said, the majority of persons who are bitten escape, and hence the success of vaunted specifics which have been in vogue from the days of Mithridates down to the present day. No bad result can follow, as we have said, from the bite of a healthy dog, except an unpleasant injury, though every wound should be attended to promptly, and all reasonable precautions adopted. The animal which inflicted the bite should be watched, in order to ascertain accurately the state of its health ; when proved healthy, the patient will be relieved of the feeling of suspense, and will know with certainty that rabies cannot follow. Dogs will bite if they are teazed, and we are apt too often to forget this. They are loving, affectionate, and much-enduring animals, but their endurance is oftentimes sorely taxed ; we have many times felt astonishment that dogs have so patiently allowed their tails or ears to be pulled, and other torments inflicted on them, without retaliation, and we cannot too strongly impress the duty, dog owners owe to these animals, of treating them with kindness and consideration. If dogs are kept for use they are valuable—if for pleasure, they are a source of enjoyment, and on either ground we should have a personal interest in their well-being; they should be regularly fed, and supplied with water, and it is greater cruelty, than was ever performed by any vivisectionist to keep an animal for months in a half-starved condition. Statistics show that a large number are bitten annually without any bad results, and also that a large number are bitten by rabid animals with immunity, and that this immunity is secured by attention to the wound. The older writers, as Etmullerus (*b*), recognised two periods of time in this affection—

1. That of receiving the first hurt or wound.
2. That of the supervening rabies.

Etmullerus also recognised that if taken at the beginning it may be cured with proper remedies.

Preservative measures will subsequently receive our attention ; at present we shall confine ourselves to some statistics bearing on the proportionate number of persons bitten and the comparative mortality.

From Zurich (*a*) we have returns of 233 persons who were bitten by rabid animals in a period of forty-two years. Of this number only 4 died, 2 of whom were bitten in parts where preservative measures could not be adopted.

The Zurich plan of treatment consisted, in scarification of the bite, application of pulvis lyttae, mercury. The wound was kept open for the space of six weeks.

Wendt, of Breslau, treated 106 persons bitten by mad animals between the years 1810 and 1823. Out of this number 2 died. He also attended 78 others who were bitten by animals not rabid.

Wendt kept the wound open for six weeks, and filled it with powdered cantharides.

Ekstrom (*b*) reported an epidemic of rabies at Stockholm, which occurred in the year 1821. The account was drawn up at the request of Henry Earle, and is interesting as Ekstrom also suggests the idea that the poison is not received into the system until a short time before the symptoms of rabies became manifest. He also starts the ingenious speculation, that a portion of the poison may be detained in the original wound, in consequence of condensation of the cellular membrane.

Ekstrom affords some other interesting information, as that a patient spat into his eyes, and into those of the house surgeon, without any bad result. The only remedy employed was tepid water. The same patient bit the nurse in the hand. The hot iron was immediately applied, and she suffered no further inconvenience.

Ekstrom informs us, in the spring and summer, 1824, rabies was epidemic in Stockholm, and 106 persons presented themselves at the Royal Hospital, with wounds received from the bites of animals rabid, or supposed to be so ; out of the entire number, only one afterwards suffered from the disease.

This unfortunate did not attend to his wound, and did not comply with the conditions laid down by the medical authorities. The treatment consisted in deep incisions in the wound and surrounding parts, which were then washed with water, or dilute muriatic acid, or a solution of muriate of lime. The hot iron, or *potassa fusa*, or strong muriatic acid, was then applied so as to touch every point of the bottom of the wound and incisions.

The suppurating surfaces were kept open for weeks and months by means of cantharides ointment.

Earle, surgeon to St. George's Hospital, told Youatt that nearly 4,000 persons had undergone the operation of excision, having been bitten by rabid or suspected dogs, and it was not known than any of these subsequently developed the disease.

Youatt (*c*), as we have mentioned, was bitten himself five times; and he also cauterised the wounds of 400 persons, who had been bitten by rabid animals, all of whom escaped.

John Hunter states that he knew an instance in which 21 persons were bitten, and only one died. And Vaughan, another instance in which between 20 and 30 persons were bitten by a mad dog, one of whom only perished.

Aitken (*d*) states that out of 153 persons bitten by a rabid dog, 94 are said to have died.

Tardieu mentions that in 99 individuals bitten by animals manifestedly rabid, 41 became ultimately affected.

Bouly (*e*) in his report published in 1870, has collected the histories of 320 persons bitten by rabid animals, and of these 129 perished from rabies.

According to Renault the percentage amounts to 33.

The injuries inflicted by wolves seem to have been much

(*d*) Aitken, "Practice of Medicine."
(*e*) Fleming, "Rabies and Hydrophobia."

more serious and fatal; according to Renault, out of 254 persons bitten by these animals, 164, or nearly two-thirds, died of rabies; and Troilliet (*a*) relates that out of 23 persons bitten by a wolf, 13 died.

In these cases preservative measures were not adopted, and hence the great fatality.

The letter from the secretary of the Home for Lost Dogs, Battersea Park Road, furnishes facts which should remove the fears of nervous people. Mr. Scoborio (*b*) states that nearly 95,000 dogs have been seized in the streets by the police since the enactment of the Traffic Regulation Act. Many of these animals were more or less intractable. These animals were conveyed by hand to police stations, and afterwards to the Dogs' Home, and Mr. Scoborio is authorised by Chief Inspector Harris, of Scotland Yard, to state that notwithstanding the great risk of rabies incurred by the officers engaged, and the frequency of severe bites, that dreadful malady, rabies, has never occurred in the metropolitan police, as shown by the medical returns. Furthermore, at the Home for Lost Dogs, where a stream of 1,500 dogs per month passes through the premises, and where upwards of 400 dogs are constantly kept in kennels, bites (sometimes of serious nature) are of daily occurrence; yet not once during the last seventeen years has hydrophobia resulted from any of such injuries. The head keeper (Mr. Pavitt) has been employed at the Home since its foundation, and has informed Mr. Scoborio that he has been bitten, more or less severely, hundreds of times, without ever feeling any symptom of madness, or any pain except natural suffering arising from the injury.

Since the establishment of the Home for Lost and Starving Dogs, 200,000 animals have been brought to the kennels. Not one of those dogs has been affected with rabies, although most of them were stray, starving, or vagabond animals. He thinks this disposes of the popular theory that the terrible disease alluded to is cherished only by stray dogs. It is important to note this point, because it proves that the cry of death to dogs found in the streets without owners is unjust and unreasonable. It is nevertheless true that many hundreds of "mad dogs," so called, have been brought to the home, where they have been isolated, kindly treated, and fed with appropriate food. In not one instance has rabies been discovered in such animals. Some of the cases at the time of their arrival were designated as "raving madness," and stories were told of bites by the dogs which had already resulted in hydrophobia, yet without the slightest foundation in reason. There were found symptoms of disease, but not of rabies; while proofs of alleged hydrophobia consisted of the usual vague assertions, without verifications of any kind, so far as could be ascertained. This circumstance has an important bearing on the prevailing panic. Ignorance of the real symptoms of rabies and terror of its consequences will inevitably lead to atrocities in our streets. A fit is not a symptom of rabies, as is popularly supposed, and no alarm ought to be felt by the public when they see a convulsed dog in the street. Unfortunately, people do not stop to reason, but give way to their fears when they see such an occurrence, and the poor brute is consequently driven up one street and down another at his utmost speed, kicked, stoned, terrorised, and maddened into fury, until he bites some one obstructing or pursuing him, whereupon without further evidence, he is pronounced to be mad.

We must ask for consideration for our friend the dog, and for our readers to calmly weigh this sensible letter. Goldsmith evidently must have witnessed, or imagined, some such panic, as we are now passing through, when he wrote the following satire, a satire so gentle, and yet so true, that probably a large number will have read it, without ever seeing its point. We need hardly make an excuse for reproducing it:—

(*a*) "Nouv. Traité de la rage," 1820.
(*b*) Letter, *Standard*, Nov. 19, 1877.

AN ELEGY ON THE DEATH OF A MAD DOG.

Good people all of every sort
Give ear unto my song,
And if you find it wondrous short,
It cannot hold you long.

In Islington there was a man
Of whom the world might say,
That still a godly race he ran
When'er he went to pray.

A kind and gentle heart he had
To comfort friends and foes;
The naked every day he clad
When he put on his clothes.

And in that town a dog was found,
As many dogs there be,
Both mongrel, puppy, whelp, and hound,
And curs of low degree.

This dog and man at first were friends,
But when a *pique* began,
The dog to gain his private ends,
Went mad and bit the man.

Around from all the neighbouring streets
The wondering neighbours ran,
And swore the dog had lost his wits
To bite so good a man.

The wound it seemed both sore and sad
To every Christian eye;
And while they swore the dog was mad,
They swore the man would die.

But soon a wonder came to light,
That showed the rogues they lied;
The man recovered of his bite,
The dog it was that died.

Influence of Sex and Age and Seat of Injury on Transmission and Mortality.

We have already mentioned that the male sex appears most exposed to the dangers of rabies. The following brief statistics will still further confirm this. (*a*) In England from 1847 to 1858, 133 deaths took place from rabies—viz., 103 males and 30 females. From the Departmental Reports compiled in France, from 1850 to 1859, we also learn that the proportion was as follows:—Males, 175, females, 64. In Bouley's analyses of 320 persons bitten, 206 belonged to the male sex, and 81 female, the sex not being indicated in the remaining 33.

Age.—We have already alluded, in the last chapter, to this subject, in connection with the mortality, and add a further contribution to it. In England in 1866, the number of deaths being 36, the ages were as follows:—

Under	5	years		-	6
From	5	to	10	-	9
,,	10	,,	15	-	2
,,	15	,,	20	-	4
,,	20	,,	25	-	4
,,	25	,,	30	-	5
,,	30	,,	40	-	2
,,	50	,,	60	-	2
,,	60	,,	80	-	2

Boudin gives the following ages of 136 persons who died from rabies in France:—

Under	5	years		-	7
From	5	to	15	-	30
,,	15	,,	20	-	15
,,	20	,,	30	-	12
,,	36	,,	60	-	54
,,	60	,,	70	-	8
,,	70	upwards		-	6

Bouley gives the ages in 124 cases, from which we find that the largest number of accidents, 97 out of 174, occurred between the ages 5 to 15.

(*a*) Fleming, "Rabies and Hydrophobia."

Children we know thoughtlessly and imprudently play with animals and tease them, and even with strange dogs they are inclined to endeavour to make friends.

Seat of Injury.—Statistics afford ample evidence that bites inflcted by rabid animals upon uncovered parts of the body, such as the face and hands, are much more disastrous than when the teeth have had to penetrate the clothing.

Wounds on the face, especially, seem most dangerous ; hence the mortality from the wounds of rabid wolves which generally fly at the face of those persons whom they attack. French statistics on this point are almost conclusive.

In forming our prognosis, we shall have to consider these circumstances, as the nature of the animal, the structure of the teeth, the size of the wounds, number, extent, and depth, as well as the nature of the parts involved. (*a*) These shall receive more extensive consideration when we are speaking of the preservative measures necessary in every case, where the bite of an animal has been received. We now leave the theoretical, and must next consider the practical questions : when the diagnosis of rabies in the human being is clearly established, can we hold out the faintest hope of recovery, or must we, as Romberg says, advise the patient to make "meditationes mortis?"

As "heirs to all the ages," with the wealth of medical literature we possess on this subject, with the accumulated experience of some thousands of years, with the facts and evidence we have collected, must we confess that medicine is impotent, and that a case of recovery has never been recorded?

Can we only endorse the opinion that death is the physician that cures, ἰατρος ιατρει θανατος, and that we can only promote the patient's euthanasia, in a manner certainly more scientific and more humane than the smothering practices of our ancestors—that our only resort is to poison the patient, *cito tuto et jucunde*, by chloroform or chloral hydrate?

We must emphatically assert that cases of recovery have been recorded, and have taken place ; that the evidence on this point is as conclusive as the evidence that such a disease as rabies exists ; and to deny the existence of such records of recovery, is simply to deny the existence of the disease. We can only know rabies by the symptoms, and by the description we have furnished by those who have had cases under treatment.

If the evidence is satisfactory and conclusive that rabies has existed, and unfortunately been too fatal, it is also equally satisfactory and conclusive that Dr. Offenberg has described the disease, and attended a patient who recovered ; that Dr. Austin Flint has offered similar testimony ; and that Professor Polli has contributed his quota to this gratifying and consolatory register.

We are not enthusiastic on the subject of the efficacy of *curara ;* but we feel it our duty, with the utmost deference, to enter a protest against statements which are not verified by fact, and which strike at the root of medical progress and medical science. The injurious tendency of such teaching we have had already occasion to animadvert on, and we have attributed much of our ignorance on the subject of this disease, to the influence exercised by some of the older physicians. We have demonstrated how much progress has been made even since 1870 in the morbid anatomy and pathology, and this alone should be an inducement to encourage further research.

We have shown how much we know, how much we have yet to learn ; we are willing to acknowledge our ignorance on many points, but we cannot admit the impossibility of discovering a remedy, and we are not disposed to write over the door of the patient's room the despairing and well-known lines of Dante,

Lasciate Speranza.

The treatment in the past has been, in the majority of cases, irrational and unscientific ; the majority of he deaths may be attributed as much to the bad treatment and the action of the medicines administered, as to the virus introduced into the system. Encouraged by the recoveries that have taken place, we venture to prophecy future successes, if not with *curara*, still with some other remedy, wrested by the skill of the scientist from the grand laboratory of nature. We believe that there is not a poison in existence for which there is not an antidote. We have faith in our profession, a faith not resting on the changing quicksands of medical theories or opinions, but built on the sterling triumphs of medicine over diseases, which were pronounced by our ancestors incurable.

We cannot recognise, then, in rabies any special conditions which preclude us from hoping, that the beneficence of the Evolver, which enables us to grapple with other diseases, will grant us similar power over this sad scourge of humanity and in this spirit we lay before the profession our views on treatment, curative, preservative, and preventive.

(*a*) "Rab es and Hydrophobia."

Case CXXV.—Madame M., æt. 46, bitten on her lip by her lap dog, which was rabid. Wound not cauterised for some days.

Result and Time of Attack.—Five days after. Recovery.

Treatment.—Baths, salivation, calomel.

Remarks.—"This is another doubtful case, the symptoms being such as might be expected from fright working on the imagination of a nervous hypochondriacal female."—Ed. *M. C. Review.*

Reference.—Med. Chir. Review, vol. ii., p. 499.

Case CXXVI.—Dom. Brizzi, bitten by his own dog. Wound cauterised.

Result and Time of Attack.—Six days after symptoms appeared. Recovery.

Remarks.—The dog bit master, son, and servant ; the servant's wound was not cauterised, and he died of hydrophobia in the course of two or three days.

Reference.—Med. Chir. Review, vol. iii., p. 299, *Storia Medica Ch. un Caso Raro.* Dr. L. Emiliani.

Case CXXVII.— ——, male, bitten on wrist and hand. Wound excised. He was desirous of having the arm amputated. He was able to swallow liquids almost to the last.

Result and Time of Attack.—Eleven months afterwards. Fatal in three days.

Treatment.—Opium, colchicum.

Post-mortem.—A most minute and faithful account given of *autopsy*, part of which we copy :—The dura mater was preternaturally vascular, the arachnoid opaque, and the pia mater presented a complete mass of highly injected blood-vessels. The medullary structure of the brain showed a number of bloody points, the theca vertebralis was vascular. Neck and arm : The par vargum manifested a general blush of inflammation, the sheath of the nerve injected with blood-vessels, and small vessels were observed running parallel. The fourth, fifth, sixth, and seventh cervical nerves highly injected, and some of them were so much altered in character as to resemble muscular fibres ; their external surface was almost scarlet, while the internal was of a pink colour. The branches of the cutaneous nerves leading up from the cicatrix, which was vascular, and had been painful, presented the same appearance. The lining membrane of the mouth inflamed. The larynx, pharynx, trachea, fauces, uvula inflamed. The œsophagus, especially near the cardia, was very vascular, the lungs congested. Some patches of inflammation were seen on the surface of the stomach. The intestines were natural, the other viscera natural. Spine : The theca vertebralis was covered with injected blood-vessels. The medulla spinalis was natural, but evident appearances of inflammation were visible at the origin of all the cervical nerves in it. The pelvic nerves did not present the appearances found in the other nerves. The autopsy was made by Mr. Bickersteth and Mr. Hatton, and lasted six hours.

Reference.—Med. Chir. Review, vol. iii., p. 534. 1825. Dr. Bickersteth.

Case CXXVIII.— ——, male, bitten by a mad dog in Nov., 1823.

Result and Time of Attack.—Eleven months afterwards. Fatal, in twenty-four hours after the first symptoms appeared.

Post-mortem.—The vessels of the brain injected, sinuses filled with blood. There was half an ounce of serous effusion

in the ventricles. Perforation of the stomach capable of admitting the closed hand, from which a clear coloured fluid had escaped into the abdomen. The pericardium was highly vascular, the whole pharynx inflamed, and the back of the throat was covered with bloody frothy mucus. The lower part of the œsophagus was deprived of its mucous membrane.

Treatment.—Injection of morphia and warm water into the veins after the system recommended by Mr. Booth, of Birmingham, and practised by Majendie "on a case now allowed not to have been hydrophobia at all, but a spontaneous disease resembling rabies canina."—ED. *M. R. C.*

Reference.—*Med. Chir. Review*, vol. iii., p. 571-575. Dr. Brandreth.

CASE CXXIX.— ——, boy, æt. 14, bitten by a dog, state unknown. Wound cauterized with red-hot iron; blister kept on the parts.

Result and Time of Attack.—Seven weeks after. Fatal.

Treatment.—Injection of vinegar per rectum, and also given by the mouth.

Reference.—*Med. Chir. Review*, vol. iv., p. 264. 1826.

CASE CXXX.—Richard Cheshire, bitten on the hand badly by a mad dog.

Result and Time of Attack.—One month after. Fatal.

Remarks.—Dr. Iles said: I first saw deceased on Saturday afternoon. He was then lying upon his bed partially undressed. He complained of suffering from a spasmodic difficulty of breathing, which he said came on occasionally, and and from an inability to swallow liquids. I remained with him half an hour, during which time he tried to swallow a little milk. He took the vessel containing it into his hand and raised it to his mouth, but the moment the liquid touched his lips he pushed it from him and exhibited great repugnance to it, shortly after which he suffered from a spasmodic attack in the throat. On recovering, he told me, in a perfectly rational manner, that he had been severely bitten on the hands and left wrist by a dog on September 27th. He told me he was walking along the St. Alban's Road, when a black retriever dog passed him, and after it had run a few yards it turned back and walked by the side of him, smelling at his coat tails, and presently jumping on his back. He told me that he then shook a small cane he had in his hand at the dog, and said, "Get down, you brute," upon which the animal flew at him, and before he could recover or help himself in the slightest degree he had been severely bitten in the hands and wrist. Cheshire then walked on to Watford, where Mr. Rudyard, one of the resident medical men, cauterised his wounds and recommended him to go at once to University College Hospital, in London, where the operation was repeated. The only symptom of which Cheshire complained to me at this time was severe pain in the right arm extending to the shoulder. I saw the deceased later on, at 8.30 p.m. He was then raving violently, and spitting up frothy mucus. He knew the people around him, and he knew me. He tried to swallow some brandy and water, and managed to take a mouthful, but immediately ejected it with great violence. He quieted down a little after morphia had been injected under the skin, but he had a very rapid pulse, and his pupils were widely dilated. I saw him later on at 11.30 p.m. Since my last visit he had been able to swallow with great effort a little milk and a little brandy and water. He was perfectly sensible at this time, and comparatively cheerful; but his pulse was much weaker. When I left him he was trying to compose himself to sleep. I was sent for again at 4.30 a.m. on Sunday, but the poor fellow had died before I could reach his cottage. There is no doubt whatever that his death arose from hydrophobia.

Reference.—Report of inquest, Oct. 31st, 1877.

CASE CXXXI.—Elizabeth Webber, bitten through the nail of the middle finger of the right hand by a pet dog. Some boys teased the dog in the street until at last the animal, goaded to anger, turned and bit six persons. Five of them had the wounds cauterised.

Result and Time of Attack.—Died three months after in the Boston Hospital, America.

WEDNESDAY, JANUARY 2, 1878.

ANNUS MEDICUS, 1877.

THE time has again come round when it is our custom to briefly review the more important events in medical politics, literature, and science which have signalised the year just past. What has been done within the last twelve months to maintain the practice of medicine in that honourable position which it has always taken among the learned professions—what has been done to improve the standard of medical education and the position of those who have adopted the lower walks of medical life—what important discoveries or facts have added to our knowledge of the nature and treatment of disease—what medical works have enhanced the value of a literature, already rich in works of acknowledged merit?—these are some of the questions to which a brief answer must be given on the present occasion. Not that we shall be able to make any startling statement, or recall any incidents that will greatly distinguish the *Annus Medicus*, 1877, from those that have preceded it. Neither the doings of the medical world nor the progress of medical science are marked by any events that can attract much attention from those who are outside the profession. They pursue their humble course unnoticed amid the greater events of which they form so inseparable but insignificant a part. They run like streamlets amid a scene of imposing grandeur, undisturbed by the political and social tempests that rage around them, yet fertilising the ground, and contributing their mite to the "increase of man's estate." Medicine, indeed, may be said to resemble one of those great but unfinished coral reefs which have been in the course of time gradually built up by innumerable hands which have long since disappeared

from the scene of their labours—a reef, in the history of which twelve months is too short a period to have made any appreciable addition to the growth of so vast a superstructure. It is only when we take a number of years into consideration that we become sensible of the great changes that have taken place in the development of either the physical or intellectual world.

With regard to medical politics, the proceedings of the Medical Council ought first to claim our attention, not so much for what it has accomplished, as for the position it holds with regard to the medical education and registration of medical students. To promote, as far as possible, the cause of medical education, to be responsible for the teaching and examinations of the various licensing bodies, to enable the public to distinguish between educated and uneducated practitioners, to watch the progress of events which affect the public health, and to advise the Government in various questions that arise in the dominion of medical politics—these are, said the President, Dr. Acland, in his address, the chief aims for which members of the Council meet together. That they have done much towards the attainment of the object they had in view cannot be denied, but the time they have wasted in discussions on petty amendments, the wording of resolutions and irrelevant matters, has justly exposed them to the censure of their critics. During the first few days of their session they took into consideration the subject of foreign and colonial degrees, the education and registration of midwives, the territorial range of titles to practice, and Dr. Lush's Medical Acts Amendment Bill. With regard to the first of these questions, it was resolved that the Council should have authority to establish, under conditions, in the Medical Register, a distinct alphabetical section for foreigners practising in the United Kingdom with qualifications granted in foreign countries, and entitling to practise in those countries respectively; and that in this section of the Register such qualifications may be registered as the Council may judge to be sufficient guarantees of the possession by the candidate of the requisite knowledge and skill in medicine. With regard to Dr. Lush's Bill, it was resolved to postpone the introduction of more stringent penal clauses into the Medical Acts until such time as those Acts shall have received all legislative amendments in the provisions relating to the profession itself, and shall then be in readiness for consolidation. Nor was any satisfactory decision arrived at with regard to the education and examination of midwives. The Council merely resolved that means, under legal sanction, should be provided for giving credentials of qualification to competent midwives, and that the lives of women in labour should, as far as practicable, be protected from the incompetent. The most important resolutions the Council adopted were those relating to the preliminary and professional education of medical men; and which, if carried out, will have a very wholesome influence upon the education of those who are thinking of entering the medical profession. That no person can be registered as a medical student unless he has passed one of the preliminary examinations sanctioned by the Council; that these examinations should be left to the universities, and such other bodies engaged in general education as may be approved of by the Council; that the licensing bodies should themselves have an eye upon the preliminary knowledge of their candidates;—these are recommendations which, if acted upon, would certainly prevent many getting into the profession, who have hitherto been able to enter it on much too easy terms. As respects the professional education of students, it was recommended "that the professional examinations be arranged in two divisions, the first division to embrace the more elementary subjects. The first division may be completed at or before the close of the second year; but the second division not till the expiration of two years after passing of the first division, nor before the completion of the fourth year of study.' The advantages and disadvantages of this recommendation, we have exposed on a former occasion. Although this plan will compel the student to acquire by the end of his second year a more thorough knowledge of the elementary subjects, it at the same time allows him to think no more about them after he has passed his first examination, so that the last two years of his curriculum will be occupied in learning one half of his subjects and forgetting the others. It was also recommended that there should be an examination at the end of the first year; that students should be required to produce evidence of having had six months experience in the charge and treatment of patients in a hospital, dispensary, or elsewhere; and that no student should be required to attend more than one course of lectures on the same subject.

Intimately connected with the subject of medical education, is that of the Conjoint Scheme, the slow progress of which has almost exhausted the patience of the most zealous advocates of medical reform. Perhaps, however, more has been done during the past year towards the advancement of this scheme than at any previous period. At the beginning of the past year there remained a good deal of opposition and many obstacles to overcome before any unanimity could be arrived at respecting the formation of a conjoint Examining Board for England. Chief amongst them were the objections raised by the College of Physicians and the University of Cambridge. These two have been since got over; the scheme, as finally amended, was laid before, and was accepted by, the last meeting of the General Medical Council; while, within the last few days, all the co-operating bodies have severally elected their representatives on the Committee of Reference. The constitution of this Conjoint Board has been on a previous occasion explained in the columns of this journal; but we may here remind our readers that the scheme is to terminate at the end of ten years from the date of its sanction by the Medical Council, "and do then cease, unless renewed," and that the experiment is likely to be restricted to England. It is, however, to be hoped that Scotland and Ireland will soon follow the good example that has been set them by the sister country, as otherwise the object of the English Conjoint Board will be partly defeated by the liberty students will still have of getting a licence from some Northern examining body. It is to be hoped, also, that the Board will not raise its examination to too high a standard, or forget that nine-tenths of the candidates that come before them will be entering the profession with the view of practising as general practitioners.

One of the most extraordinary medical and social innovations of the present era is certainly that of the admission of women into the ranks of the medical profession. The subject has caused a good deal of embarrassment to those who have had at heart the interest of the medical profession on the one hand, and that of the public on the other. Rightly or wrongly, the fair sex have, during the past year, done much towards the realisation of their hopes and aspirations; and it is impossible to ignore the fact that the admission of women into the profession, and their eligibility as candidates for all the degrees and licences of our universities and examining boards, have almost become *un fait accompli*. And here we may briefly recall attention to one of the little episodes that have occurred in the battle that has been recently raging between the lady doctors and their rough and ungracious opponents. That there are few quarrels in which there is not a woman at the bottom of it, it is pretty generally acknowledged; but who, fifty years ago, would have thought that the gravity and harmony of the Senate and Convocation of the University of London would be grievously upset by a question involving not only the right of women to enter the medical profession, but to share all the privileges accorded to the male graduates of the University. The extraordinary dispute that has been going on for some time between the Senate and Convocation arose out of the determination on the part of the Senate to disregard both the opinions which Convocation had expressed on the matter, and a memorial that had been presented to them by the medical graduates of the University. At one of the meetings of Convocation Mr. Savory had moved an amendment, the propriety of which few will be inclined to dispute—viz., "That this House is of opinion that it is undesirable for this University to admit women to degrees in medicine before it shall have considered the advisability of admitting women to degrees in all the faculties." This amendment was well supported, and carried by 144 to 116; but, nevertheless, the Senate disregarded the decision of Convocation, and decided to take advantage of Mr. Russell Gurney's Act, 1876, and admit women to examinations for its medical degrees. The question then very naturally arose as to whether the Senate was to take the lead in coming to a decision of so much moment, and whether the privileges of Convocation had not been infringed by the action of the Senate, by which action "the constitution of the University would be materially altered, without consultation with Convocation." Consequently a general meeting of Convocation was held in July, which resulted in its condemning by a large majority the adoption by the Senate of a permissive Act of Parliament without reference to Convocation, a condemnation that was strengthened by a legal opinion to the effect that the Senate by acting upon their decision would be changing the constitution of the University, contrary to the spirit of its charter. Subsequently, after a meeting of the Annual Committee, and after much correspondence, and one or two deputations on the subject, the Senate expressed their willingness to apply for a supplemental charter which should admit women to degrees in all faculties, and hoped that Convocation would co-operate with the Senate in carrying their proposal into effect. The dispute, however, is even now, far from having been satisfactorily settled; for at their last meeting in December the Senate, in reply to a message received from the Annual Committee, said that although they hoped the question would be settled in a manner that was satisfactory to both parties, they "at the same time felt it necessary to point out that they have not taken any resolution as to their future course of action."

The Legislature gave so little attention last year to sanitary legislation that a very few remarks will suffice on this point. Unquestionably, the most important measure was the appointment of a Select Committee to inquire into the operation of the lunacy laws as regards the security afforded against the violation of personal liberty. A large Blue Book containing the evidence of the Committee was issued at the end of the session, but on account of time being required to digest its voluminous and contradictory contents, the Report of the Committee was deferred to the present year. A Bill to Consolidate and Amend the Acts relating to Public Health in Ireland was so far successful as to pass through a Select Committee, chiefly in consequence of the praiseworthy exertions and representations of the King and Queen's College of Physicians, the Royal College of Surgeons of Ireland, and the Irish Medical Association. Unfortunately, however, it failed to get into Committee of the House of Commons. The only measure that did pass was the "Canal Boats Act, 1877," which will certainly do some good by checking the diffusion of infectious diseases by the constant movement of those boats. Some experimental steps were also taken with respect to the registration of infectious sickness, Bolton (Lancashire) and Greenock being the localities in which the experiment is to be at first tried.

Nor is there much to say with regard to the changes that have taken place in respect of the Army and Navy Medical Services. In the beginning of the year an order was issued exempting medical officers in the Army from all contributions to regimental messes and bands, and they were also authorised to draw staff instead of regimental allowances. In September, also, the new Royal Warrant for regulating the organisation of the Army Medical Corps contained a clause which, for the time, gave the medical officer the right of commanding in the military hospitals, of commanding the "non-commissioned officers and the privates of the Army Medical Corps, and all patients in military hospitals, &c." The medical officer in charge of a hospital is also not now expected to look after its necessary equipment and supplies, as this duty is to be henceforward entrusted to the officers of the Army Hospital Corps.

We can only briefly allude to the transaction of the Royal College of Physicians and Royal College of Surgeons. The former body has passed an important and favourable by-law, with regard to the admission of foreign candidates to its examinations. A new and revised edition of the "Nomenclature of Diseases" is in course of preparation; and its Leprosy Committee has made some valuable reports on the treatment of that disease. The College of Surgeons has approved a Bill for the registration of all dentists irrespective of any qualification, except that of having been engaged in the practice of dentistry for a certain time. The proposed alterations in the by-

laws relating to the Fellowship have been postponed in deference to the wishes of a large number of Fellows; and on the proposal of Mr. Marshall, the Council has agreed to elect each year two members to the Fellowship, subject to certain conditions.

A glance at the last meeting of the British Medical Association, may well usher in the few remarks we have to make on the scientific aspect of the past year. Undoubtedly, the most interesting address delivered on that occasion, was that of Dr. W. Roberts on "The Doctrine of Contagium Vivum, and its Application to Medicine." In this address he endeavoured to prove that organic matter has no inherent power of generating bacteria, and no inherent power of passing into decomposition, that bacteria are the actual agents of decomposition, and that those organisms which appear as if spontaneously in decomposing fluids owe their origin exclusively to parent germs, derived from the surrounding media. To Mr. Spencer Wells' Address on Surgery we have already drawn special atttention, and another suggestive address was that of Dr. Barnes, on Obstetric Medicine, in which he protested against the tendency now-a-days to "split up the study of the healing art into sections, to the neglect of those grander lights which can only be caught by a well-balanced study of all in their mutual relations." Several other valuable papers or addresses were read, and altogether the last meeting of the Association was a successful one. It is scarcely within our province to notice here the British Association for the Advancement of Science, but we cannot help reminding the reader of the able address of its President, Dr. Allen Thomson, the well-known embryologist, in which the author stated his conviction that the investigations of the last seven years have been unfavourable to the doctrine of spontaneous generation (thus endorsing the opinion of Dr. W. Roberts aboved noticed); but that, on the other hand, there were few naturalists now living, who did not believe in the doctrine of evolution.

The work done at the Medical Societies can scarcely be ignored in an annual retrospect of scientific medicine. It is remarkable that the papers read at the Royal Medical and Chirurgical Society, dealt chiefly with rare and obscure questions of pathology. A rare form of Neurosis without suppuration (Morrant Baker); the pathology of Tetanus and Hydrophobia (Coats); a case of Noma in which moving particles were found in the blood (Sansom); a rare condition of the skin called Myxœdema (Dr. Ord); and the pathology of Sclerema (Dr. Harley); these were the kind of subjects which last year chiefly engaged the attention of the Society. On the other hand, the work done at the Clinical Society, of which full reports have been given in these columns, has been more of a surgical than medical or therapeutical nature. Good papers, however, were read by Dr. Murchison on a case of enteric fever treated by Salicylic Acid; by Dr. Broadbent on the value of Bleeding in Convulsions; by Drs. Herman, Weber, and Cavafy, on the treatment of Rheumatic Fever by Salicin; and by Dr. Southey on a method of draining anasarcous limbs by means of a small trocar and tube. Cases of sub-periosteal surgery, the merits of the carbolised catgut ligature, and cases of unilateral injury to the spinal cord (Gowers); hydatids of the lung (Greenfield); and hysterical anæsthesia (Dr. Henry Thompson), were likewise subjects of discussion before this society. Unquestionably the most important subject that received the attention of the Pathological Society was that of Visceral Syphilis. We have already commented on the valuable information that was given on this obscure department of pathology, and to our articles on this interesting subject we must refer the reader who wishes to become more particularly acquainted with the morbid anatomy and symptoms of cerebral and pulmonary syphilis. The consideration of arterio-capillary fibrosis (Gull and Sutton); of the arterial changes in chronic Bright's disease (George Johnson); of the early changes in scarlatina (Klein); of the nature of contagium (Braidwood and Vacher); and, very recently, of lactic fermentation (Lister), also occupied the attention of the Society. Lastly, we may mention that many valuable papers were read at the Medical, Obstetrical, and Harveian Societies, which want of space prevents us from particularising.

The general advancement of medicine and surgery has been accelerated by much valuable work and many careful researches. In pathology fresh light has been thrown upon the relation of minute organisms to acute infectious disease, by the experimental researches of Dr. Burdon Sanderson, Pasteur, and Dr. W. Roberts; upon diseases of the brain and nervous system, by the researches of Charcot, Brown-Séquard, and others; and upon the pathology of pernicious anæmia of the arterial lesions in syphilis, of certain changes in the minute structure of the kidneys, &c. In the domain of therapeutics there is much upon which the profession can look with satisfaction. During the past year a large amount of evidence has accumulated in favour of the therapeutic efficacy of salicylic acid or salicin in rheumatic fever, while it has also been found useful in some cases of ague, typhoid fever, coryza, and neuralgia; the administration of ergot by the hypodermic injection of ergotine; the value of this medicine in labour, and in the treatment of hæmoptysis; the value of cold baths in the treatment of rheumatic fever, and other diseases attended with hyperpyrexia; a more exact and temperate estimate of the efficacy of chloral hydrate in the treatment of disease; these are among the more important additions to our knowledge of practical therapeutics. It need scarcely be said that the most brilliant and practical department of medicine—Surgery—would be behind-hand in its contributions to the past year. In the hands of Mr. Spencer Wells and other surgeons, the operation of ovariotomy has been brought to a state of great perfection, and has been attended with greater success; while various methods of successfully dealing with aneurisms, and several new, rare, or bold and successful operations have shown that surgery continues to take the lead in effecting those surprising cures which have always made it the most admirable and most popular department of the healing art. We intended to have specified some of the more important works that have been recently added to our medical literature, but the length to which this article has already been brought, forbids us doing more than mention the fact that very few great or valuable works have been published within the last twelve months. Nor should it be forgotten that the most valuable additions to our knowledge of disease are not to be found so much in the published works whose names figure

in the advertising columns of this and other journals, as in those numerous and valuable paper, lectures, and monographs that are scattered through the pages of our periodical literature.

Before concluding this brief and imperfect notice of the medical history of the past year, we cannot help mentioning one or two minor incidents that have recently attracted a great deal of public attention. We allude more particularly to the prevalence of hydrophobia, to the "Bradlaugh Trial," and to the Penge case. The epidemic prevalence of hydrophobia is one of those events which remind us that there are some diseases to which the profession has not given so much attention as was desirable. Naturally enough, a great deal has been said and written on the subject, but without adding much to our previous knowledge of the disease. In consequence of the public excitement on the subject, we have deemed it advisable to issue a Special Report on Hydrophobia, which, we hope, will be found as complete and exhaustive as the importance of the occasion demanded. Some special experimental researches are also being conducted on the pathology of the disease, under the able superintendence of Dr. Burdon Sanderson; and therefore, while the recent outbreak of this terrible malady has already given an impetus to original research into its nature and treatment, it has also induced the authorities to adopt more stringent preventive measures than have hitherto been obtained.

The Bradlaugh Trial was one of those ugly blots which, from time to time, disfigure the face of modern Society. In a leading article on the subject, we gave expression to our opinion of a pamphlet, the obscenity and immoral tendency of which did not prevent a woman personally defending it in open court; and all we have to say now is to express our satisfaction at the fact that the doctrines so shamelessly advanced by Mr. Bradlaugh and Mrs. Besant were all but unanimously repudiated by the profession.

The particulars of the Penge Case must be so fresh in the memory of our readers that any further comments than those we made at the time are scarcely necessary. From the very first we took that view of it which was most in accordance with the whole evidence adduced at the trial, and although this view was directly opposed to that which was taken by most of our contemporaries, as well as by several eminent pathologists, we were not surprised to find that a similar view of the case was taken by the Home Secretary himself, and the learned judges whom he consulted. Consequently, although one of the convicts was set at liberty, sentence of penal servitude for life was passed upon the three other defendants.

Lastly, we must not forget the gaps which Death has made during the past twelve months in the ranks of our profession. The first to go was Dr. Snow Beck, whose work on jurisprudence was long a standard work on the subject. Then followed Professor Murphy, the able and accomplished obstetrician; and after him Alfred Smee and John Adams, both eminent surgeons. But, perhaps, the greatest loss of all was that of William Fergusson, of whom it might be said, we shall "ne'er look on his like again." It will be long before practical and operative surgery has such a representative as it had in him. We might also have mentioned the names of Dr. Robert Lee, Dr. Basham, Dr. Francis Hawkins, and several others, some of whom died at a ripe old age, while others were called away in thir prime.

> "He was a man, take him for all in all,
> We shall not look upon his like again."

THE EXCESSIVE MORTALITY IN DUBLIN.

We informed our readers a fortnight since that the extraordinarily high death-rate of Dublin had moved the Dublin Sanitary Association to stir up the Public Health Committee of the Corporation, who in turn had applied to their Medical Sanitary Officers for their opinions on the subject, and that these reports, though we have reason to believe them emphatic as to the causes of the excessive mortality, had not been made public by the Corporation Committee. The Sanitary Association has, however, sent to the Committee a very important report, in which the appointment of a commission of inquiry was suggested, and this report has been answered by a counter-statement from the Superintendent Medical Officer of Health and by a resolution of the Committee, in which they decline to encourage any inquiry into the subject. The report of the Sanitary Association is substantially as follows:—

The average death-rate of Dublin city for the 47 weeks ending 24th of November, 1877, is 28·6 per 1,000, and ranks second among 13 large towns of the United Kingdom—Salford exceeding it by ·2 per 1,000. The average death-rate of the Dublin Registration District for the same period is 26·6 per 1,000, and ranks third among these 13 large towns, being exceeded by Manchester (27·3), and Salford (28·8).

The average death-rate of Dublin City for the past ten years (ending 1877) has been 27·9 per 1,000, and ranks fifth among 13 large towns of the United Kingdom. The average death-rate of Dublin Registration District for the same period has been 25·9 per 1,000, and ranks eighth among these towns.

It will be thus seen that during the present year the death-rate of Dublin City has risen from an average, during the past ten years, of 27·9 to 28·6 per 1,000 and from the fifth place, in point of mortality among thirteen large towns, to the second, and that the rate of the Dublin Registration District has risen from an average, during the past ten years, of 25·9 to 26·6 per 1,000, and from the eighth place to the third place among these towns; while, on the other hand, the death-rates of the twelve other large towns for the present year are less than the average rates of those towns for the past ten years by an average of 2·8 per 1,000.

It is to be observed that in calculating the death-rate of Dublin for the year 1877, the deaths of persons admitted into public institutions have been for the first time omitted. If, therefore, the rates had been calculated on the old basis, they would have been considerably higher.

In addition, it is notorious that the registration of deaths in Dublin is extremely defective, so much so that the average per-centage of deaths unregistered for the seven years ending 1870 was 9·8; while in the other towns of the United Kingdom this imperfect registration is almost impossible, as the burial laws require a certificate of registration of death before interment.

It will be seen from page 65 of your Report for 1875, that during the visitation of epidemics Dublin suffers with exceptional severity. Thus, in the epidemic of cholera in the year 1866, the zymotic death-rate in Dublin was 9 0 per 1,000; in London, 7·8 per 1,000. Again, in the small-pox epidemic (1871-2), the zymotic death-rate in Dublin was 8·4 per 1,000, and in London, 7·0 per 1,000. This fact argues a low state of health among the inhabitants of the city.

It was necessary, of course, that so alarming a statement as this should be specially dealt with by the Medical Superintendent Officer of Health, and accordingly a report was submitted by him, of which the following are the principal paragraphs:—

In the Report of the Sanitary Association, the mortality by the cholera of 1866 is quoted as comparatively high, but it is forgotten that our pure water supply was not then available, and that your Committee was only then formed.

The other unfavourable instance called up is the death-rate during the small-pox epidemic of 1871-2, but it is not noted that during the present year, although there have been several scattered cases. it has not assumed an epidemic character.

Another favourable item, the really crucial test of the effective action of sanitary authorities, escapes attention, namely, the lowering of deaths by zymotics in general, which, if deaths by measles be substracted, is most remarkable.

The zymotics of 1876 were 468 less than those of the average of the ten previous years, and those of the first nine months of the present year 207 less than the average of the corresponding period for ten years. Measles caused nearly one-third of the fatal zymotics of the present year ; there are no practical means of checking its spread, but its mortality can be lowered by the same measures which control the fatality of lung diseases.

Fevers and diarrhœa are the maladies which point to bad water, imperfect sewerage and neglect in removing nuisances, the chief shortcomings of sanitary authorities.

For the past and present years these diseases are below average. Our water supply and improving main sewer system must be credited with this result, which would have been more striking if individual householders gave aid in the improvement of private sewers.

The evident causes of our high death-rate are diseases of the breathing organs, and measles and whooping cough, which kill in the same way. The past summer, unprecedented for inclemency, was especially fatal to the poor in the extremes of life. Nearly one-third of the whole deaths of the first nine months of 1877 were due to the maladies just named, including pulmonary consumption.

The conditions of poverty, which are more active in Dublin than in English cities, are dilapidated, ill-constructed houses, which prevent easy passage of air and shut out sunlight, and which it was impossible to control for want of a Building Act, such as other cities possess ; scanty clothing, especially at night, neglect of ablution, insufficient food, and, it is to be feared, intemperance. A drunkard getting inflammation of the lungs surely dies. Moreover, there is no town in which there is a greater congregation of the poor and infirm from districts outside it.

The criticism on this report, which will at once occur to the reader, is that it affords no answer at all to the statement of the Sanitary Association, and not only suggests no remedy for the melancholy loss of life in the city but seems to pooh-pooh any effort to mitigate evil. This is a policy quite characteristic of the Public Health Committee, who have always been wont to answer all remonstrances by saying that their sanitary organisation was as nearly perfect as possible, and quite above criticism, and that if the dirty people of Dublin would die by hundreds the Committee could not really be expected to help them—that, after all, such people had no business to die of little ailments like pneumonia and bronchitis, and, as for fevers and such other diseases, Dublin was not much worse off than other very dirty places ; and—to make a long story short—they wish that Associations and other fussy people would not bother them with any of their nasty statistics or uncomfortable reminders.

It will be observed that Dr. Mapother, in his report, carefully avoids extending his vision beyond the present condition of things, which he endeavours to show represents only a temporary perturbation of the sanitary atmosphere. He takes credit for the non-extension of the small-pox during 1877, and for a decrease of zymotics as compared with 1876, but he does not seem to realise that the excessive mortality of Dublin has existed for twenty years or longer, and has gradually and steadily increased during the last ten, and, therefore, that this fact cannot be upset by any argument as to the special mortality of 1877.

Moreover, to plead that the zymotic fatality of Dublin is less than it was twelve months ago is of no value as an argument, for we are not comparing Dublin with Dublin, but with thirteen large towns elsewhere, and we want to know why the city should be constantly and obviously worse in health than these? If Dr. Mapother answers that it is because the city has no Building Act, we ask, whose fault is it that it has none? The Corporation's. If he pleads that great things will be done by the Artizans' Dwellings Act when it is made use of, we want to know who is responsible that it is *not* made use of? The Corporations.

There are, however, causes of disease more easily understood, and remedies less expensive and more easy, than the getting or application of Acts of Parliament, to which we invite the attention of the Public Health Committee and Dr. Mapother.

A few occur to us :—

1. Want of zeal and activity in the Public Health Committee in dealing with the money-grinding tenement farmers, who from year to year omit and refuse to provide sanitary accommodation for the miserable tenants from whom they screw exorbitant rents.

2. The leaving of street filth and offal festering under the summer sun for days together, especially in the lanes and alleys in which scavenging is most needed and least visible.

3. The omission to ventilate the sewers and keep them properly cleaned.

4. The utter neglect of ash-pit cleaning and the ludicrous impracticability of the attempt of the Corporation in that direction.

A Building Act would be valuable—in fact, it is a disgrace to such a city as Dublin to be without one ; improved artisan's dwellings would be a most important item in sanitary reform, but neither of these, nor both of them, would produce a sensible result on the health of the city unless the Public Health Committee can be first made to understand that the sanitary state of Dublin is simply abominable and disgraceful, and admits of no real defence, and, secondly, induced to attack the evil with vigour, and to put all the resources at their command into active work to remedy it. It is too evident that, at present, they are in no such frame of mind. If they were, they would be thankful for the co-operation of the public—desirous of investigation,—ready to look the evils in the face and to see their extent,—and disposed to grapple with them by a steadily-sustained effort. Instead of this, we regret to find them looking at every suggestion offered to them as an encroachment upon their privileges, and, as such, to be resented and resisted—fishing out pleas for the excessive mortality and reasons for thinking it not so bad as it might be—opposing all extraneous inquiry, and omitting to inquire themselves, and habitually contenting themselves with the most lethargic discharge of their duties.

THE DUBLIN UNIVERSITY MEDICAL SCHOOL AND SIR PATRICK DUN'S HOSPITAL.

THE proceedings of the Irish College of Physicians, to which we referred some weeks ago—their decision that it should no longer be necessary for a King's Professor in the School of Physic to resign any hospital which he may hold at the time of his professional appointment—and their subsequent reversal of that decision at the bidding of the Board of Trinity College—these matters are the subject of a long editorial article in the *British Medical Journal* of last week, in which the views we then expressed are endorsed. Our contemporary says :—

There need be no objection to the intimate association of the School of Physic in Ireland with a clinical hospital, but there is an obvious objection to the greatest school of medicine in Ireland being weighted by so incomplete a clinical hospital as that of Sir Patrick Dun to suit the views of a few college dons and the protests of those who happen at present to hold professorships in the School of Physic. Since the rule was passed, there have been two elections for King's professorships. The result of the competitions has been to show that the physicians to the Dublin hospitals will not abandon their large clinical experience to accept (with their honours and emoluments) the King's professorships, subject to the incubus of Sir Patrick Dun's Hospital. It is remarkable that three-quarters of a century ago it was considered essential to have at least thirty beds for clinical instruction in medicine alone at Sir Patrick Dun's Hospital, to be increased to one hundred to make it complete; but now no more than fifty are considered quite a sufficient field for instruction by the professional board of Trinity College, Dublin. The medical students of Trinity College, however, are wiser than their masters, and all, except a few, go elsewhere to obtain clinical knowledge; thus, of three hundred students in medicine stated to be attending Trinity College, we hear that but forty or thereabouts are satisfied with the experience afforded by Sir Patrick Dun's Hospital. If Trinity College wishes for a school of clinical medicine, let her contribute to found a hospital similar to those of King's or University College, and then there will be no need of a coercive law to prevent her professors from accepting appointments outside her walls. It is with great regret that we find a medical corporation like the King and Queen's College of Physicians lending itself to support the whims of the old Board of Trinity College, Dublin; and it would be well for the College to consider that the action they have just taken is tantamount to the expression of the opinion that the highest class physicians—namely, the university graduates—need only the smallest amount of clinical instruction.

Since the above remarks were written, a report has reached us that the Board of Trinity College, rightly calculating that their victory over the party of progress in the College of Physicians must be short-lived, and admitting the inefficiency of the clinical school of Sir Patrick Dun's Hospital, have determined to increase the accommodation at the expense of the funds of Trinity College. We hear, however, that the proposed increase will amount to thirty beds only. Such a small addition will be quite inadequate, and cannot remove the objection to the smallness of the field of clinical experience. It is argued that eighty beds will place Sir P. Dun's in a better position than several other clinical hospitals of Dublin. Such an argument is quite invalid, as the School of Physic should equal the best, not merely reach the mediocre clinical schools of Dublin.

Our own view on this subject is wider than that adopted by the *British Medical Journal*, for we object strongly to the perpetuation of a special compulsory connection of *any* hospital, however efficient, with the University School, and we deprecate the handicapping of the professors in that School by insisting that they shall confine themselves to a particular hospital and disconnect themselves for ever from other institutions where their opportunities for work may be far greater.

The affiliation of Sir Patrick Dun's with the School of Physic is a relic of the time when clinical teaching was not to be had, and when the School had no resource but to make and maintain an hospital for itself. That time has passed away, and the University students can now obtain the required instruction in much larger, and, at least, as well officered hospitals elsewhere; and we submit it is not at all to their advantage that they should be encouraged to follow the same teacher from lecture-room to bedside and back again, or to confine their learning within the narrow circle of his attainments. Free trade in hospital teaching is a golden principle, and, we fancy, the Medical Registrar for Trinity College would be the first to overthrow a special monopoly maintained in favour of any hospital, if that monopoly existed in connection with any school but his own.

The Board of Trinity College have taken a retrograde step if they have decided, as our contemporary says, to subsidise Sir Patrick Dun's for the purchase of additional beds; for they may be assured that if an hospital fails to attract students by the value of its teaching when enjoying such exceptional advantages as Dun's possesses, the addition of a few beds to its wards will not make it more popular. On the contrary, the best stimulus to such an institution would be to throw it solely on its own resources, and thus impose upon its teaching staff a supreme inducement to "give value" to the pupil.

An important lesson which may be learned from the controversy is, that the legal tie between the Board of Trinity College, a conclave of eminently respectable but dictinctly unprogressive elderly clergymen, and the Fellows of the Irish College, numbering many of the most intelligent and liberally-minded of the new school of physicians in Ireland, cannot be long maintained. The time has passed when divided empire can continue to exist in the administration of a great medical school or in the appointment of its professors, for it seems to us a *reductio ad absurdum* that the deliberate judgment of long-headed and experienced physicians and teachers in a matter which vitally concerns the efficiency of medical teaching in Ireland should be subjected to the veto of seven gentlemen of gravely academic but somewhat unpractical mind, whose interest in medical teaching is confined to maintaining all that their fathers maintained before them.

The College of Physicians is humiliated by the revision of its decisions by so unsympathetic a tribunal, and its interests are imperilled by the drag thus put upon its onward progress. If that obstruction cannot be otherwise removed we are decidedly of opinion that, by another School of Physic Amendment Act, the grounds ought to be cleared of every existing hindrance to perfect freedom of either hospital or professional tenure.

ANOTHER step in relative rank will, according to the *Army and Navy Gazette*, be shortly given to senior medical officers of the Royal Navy.

Notes on Current Topics.

The Liquefaction of Oxygen.

THE *Journal de Geneve*, furnishes some interesting particulars of one of the latest scientific achievements—the reduction into a liquid form of one of the principal constituents of the atmosphere. In an age fertile in new discoveries, the successful efforts of M. Raoul Pictet may be considered as one of the most important; and though the *telephone* may to a certain extent, by its novelty, and by its adaptability to the ordinary requirements of life, attract more popular attention, yet the scientific world will fully appreciate this latest acquisition of science. The conjecture of to-day may become the fact of to-morrow, and the mechanical theory of heat thus receives further verification, as the tendency of this new discovery is to prove, that all gases are vapours, passing through three stages—solid, liquid, and gaseous. M. Pictet has thus obtained this curious result:—By a double circulation of sulphurous and carbonic acids, the latter is liquefied, at a temperature of 65°, with a pressure of four to six atmospheres. The liquefied carbonic acid is conducted into a tube of the length of four metres; two pumps in action produce a barometric vacuum on this acid, which solidifies under the influence of pressure. In the interior of this tube, containing the solidified acid, a tube of smaller diameter is passed, wherein circulates a current of oxygen, produced, by chlorate of potass, in a generator, the form of which is an *obus*, so thick and strong as to bear a high pressure without explosion. At a pressure of 300 atmospheres a liquid jet of oxygen sprang from the extremity of the tube when the compressed gas was exposed to atmospheric pressure. The alchemists of old must have watched with feverish anxiety for the transmutation of the baser metals into gold, and with some such intense suspense must M. Pictet have waited for the appearance of the few crystal drops, which revealed to him that science had obtained another triumph.

The revelation of this event was soon known in England, for availing himself of another of the marvellous appliances of modern life, which joins country to country, and continent to continent, bringing them even within speaking distance, M. Pictet *transmitted* a *telegram*, which must have gladdened the heart of Professor Tyndall. Thus, by scientific means, unknown to, undreamt of, by our ancestors, a new scientific fact was revealed almost at the moment of its discovery, to not only the scientist in his study, but even to the civilised world.

The laws of Nature are each day being more perfectly understood; the limit of science cannot be fixed when dealing with the purely material, and we must congratulate M. Pictet upon his painstaking researches, crowned as they have been by success. Two gases yet remain for reduction into a liquid form—hydrogen and azote. We may reasonably expect a somewhat similar result in their case; if not in the laboratory of M. Pictet, at least by some of the numerous eminent chemists, who have in the present age contributed so much to the improvement of our chemical knowledge.

Drinking Fountains and Typhoid Fever.

IT is generally admitted that nervous and timid people act very imprudently when they indulge their curiosity by reading medical books. For the same reason it is equally improper for the public in general to allow their minds to be too much influenced by all they hear about the spread of contagious diseases by means of water, milk, and other vehicles of infection. A well-known daily newspaper has been taking a very hypochondriacal view of the drinking fountains of London, and because a lot of mud and filth was cleared out of the basin of a fountain near Park Lane (which was not a drinking fountain at all, but merely a disused ornamental one), it has come to the conclusion that all the drinking fountains in the metropolis will be a prolific source of typhoid fever. It is well, therefore, that the General Manager of the Metropolitan Drinking Fountains Associaton has written to say that the fears to which our contemporary had so rashly given way, were perfectly unfounded. He very properly showed that any tricks or dirty habits displayed by the London *gamins* could not possibly interfere with the purity of the water passing out of the nozzle of the fountain jet; and that the six hundred drinking fountains in London were under the almost daily inspection and superintendence of the above Association. Besides, we may remind the public that the usual position and structure of these fountains preclude them from having their water contaminated with the contagium of typhoid or any other fever. That these fountains have done a good deal towards promoting habits of temperance amongst our itinerant working population we have never for a moment doubted. Therefore, we regret that any organ of the public press should be misled by the sensational announcements that are from time to time made respecting the origin and spread of infectious disease, and that it should run the risk of prejudicing the mind of the public against one of the best sanitary improvements in the metropolis.

Arsenical Colouring of Dress.

AT this moment cotton goods printed in blue, rose, and grey colours, which contain large quantities of arsenic, are on sale in many of the drapery establishments of the Continent and this country. Examinations of them made in the laboratory of the Imperial Health Department, says the *Revue Allemande*, have established the fact that the arsenic contained in these stuffs does not come from the use of arsenical colouring matter, but from the mordants and other substances employed in their preparation.

According to the receipts deposited in the office, the preparation used for a blue, rose, or grey colour, contains a sixteenth of its whole quantity of arsenite of soda. Inasmuch as such goods may be very dangerous to the public health, the Health Department has thought it necessary to warn calico-printers and dyers against the use of such preparations, and to point out to them that there is an abundance of completely inoffensive chemicals available for the same methods of dyeing. We trust now that the danger is proved to be a real one, the inevitable lesson will not be lost upon the dyers and calico-printers of our own country.

Foucault's Pendulum.

Our readers may recollect the experiment made in 1860 at the Pantheon in Paris, by the learned Leon Foucault, upon the pendulum. A great metallic globe, which hung by a fine wire from the summit of the dome, demonstrated that the oscillatory movements of a heavy mass freely suspended in space, remain independent of the rotation of the earth. This pendulum swung very slowly in consequence of the length of the wire, and at the end of each oscillation a point attached to it ate away by degrees a little wall of sand placed there for the purpose of showing the apparent alteration in the plane of oscillation.

This experiment, by which—as we may say—the world can be seen to move round, is to be repeated in the Exhibition of 1878, with such new arrangements as to make it comprehensible to the crowd. The pendulum will be 300 killogrammes in weight, and will hang from a wire 70 metres long, the object of the experiment being to instruct the public in a visible physical phenomenon.

Isolation of Diphtheritic Patients.

The following proposal has been submitted to the Municipal Council of Paris:—Considering that for the last twenty years representations have been made by hospital surgeons in favour of the isolation of children attacked with diphtheritic diseases, which representations have had their origin in the great mortality of the little patients who have been operated often in the same apartment, in presence of other children, and exposed consequently to all the contagious diseases which exist in the general wards; considering also that a diphtheritic epidemic has existed for the last two years, which renders imminent similar unfortunate results; therefore the Council is asked to vote the establishment of isolation wards for such diseases specially reserved for children and notably in the Hospital of the Rue de Sevres.

Dr. Darby, of Bray.

The recent retirement of Dr. Darby, of Bray, from the Surgeoncy to the Rathdown Workhouse, which he had held for over thirty-five years, was, on the 22nd of December, made the occasion for the expression of kindly feelings and of respect towards him, both by the medical officers of the union and by the lay officers of the workhouse. The address from Dr. Darby's medical brethren, illuminated in an artistic and suitable manner, was presented to him, on behalf of the signatories, by Drs. Whistler, Leney, Usher, Mayne, Rice, Boyce, O'Flaherty, and Wright; and the presentation from the workhouse officers, which took the form of a handsome clock, was handed to Dr. Darby by Mr. Cope, the clerk of the union, Mr. Thompson, and the Reverend E. W. Burton.

The occasion was necessarily a touching one for the veteran surgeon, whose response was impressive and affecting. It is but scant justice to him to say, on our own behalf, that there is not a man in Ireland who has deserved better of his brethren, or enjoys their esteem in a higher degree. He has earned that esteem by nearly half a century of active sympathy with his profession, and liberal aid to the advancement of its interests; and it is gratifying to know that he lays down his official duties enjoying the uniform respect of those in whose midst his long professional service has been performed.

The Title of Doctor of Medicine.

A medical student writes from Dublin to the *Student's Journal* asking whether a College of Physician's licentiate can lawfully call himself doctor, and write himself down M.D. "To me," he says, "it seems ludicrous in the extreme that, because a man hasn't got the highest degree which it is possible for him to get, he has no title to the recognised designation of his profession."

These are words of wisdom, and the valuable principle they express ought not to be confined to the medical profession! For instance, is it not also "ludicrous in the extreme that because a (soldier) hasn't got the highest rank which it is possible for him to get" he should be denied the privilege of calling himself Field-Marshal. Perhaps this wiseacre could explain to us what might be the return which one should get for the trouble and expense of obtaining an M.D. if every general practitioner were entitled to palm himself on the public as a Doctor of Medicine. Heaven knows M.D.'s are cheap enough in certain universities just now, and no one need grumble at not being allowed a decoration which can be purchased much cheaper and more readily than a College of Physicians license. Not solid gold to be sure, but it looks quite as well, and will last until its nature is discovered.

Vaginal Hæmorrhage during Parturition.

In the current number of the *Obstetrical Journal*, Dr. Paul Budin has, through the Obstetrical Society of London, drawn attention to the fact that profuse, and even fatal, hæmorrhage may take place from the vagina after parturition, and that it may be mistaken for post-partum hæmorrhage. He had seen an artery in the perinæum spurting freely twelve hours after delivery. Lesions about the clitoris were another cause, but easy to detect. But distended veins in the vaginal wall might also burst, and this was less easy to diagnose. A case was mentioned in which a flow of vivid blood was due to a laceration in the right lateral region of the clitoris. Another case was mentioned, arising from ruptured varicose veins at both sides of the vagina. One of the members, Dr. Edis, also mentioned an instructive case which occurred in the Middlesex Hospital, in which, eight hours after delivery, flooding still continued. The patient was blanched, and the Obstetric Resident was at a loss what to do. A rent, an inch in length, was found under the clitoris, and an artery spurting. Torsion of the bleeding vessels not being practicable, the parts were plugged with perchloride of iron, with pressure.

No more Beer for Paupers.

The Medway Board of Guardians in England, enjoy the distinction of having been the first to lay the axe to the Upas trees of paupers' beer. They have ordered its total discontinuance in the case of the able-bodied, and have laid on tea as a substitute, a change in which we expect, the able-bodied will not concur.

By the will of Mrs. Julia Ann Dobie, late of No. 7 Houghton Place, Ampthill Square, who died Sept. 14, the following charities receive £300 each:—The Hospital for the Paralysed and Epileptic, Bloomsbury; the Royal Asylum of St. Anne's Society, Streatham; the Victoria Hospital for Children, Chelsea; the Royal Free Hospital, Gray's Inn Lane; University College Hospital, Gower Street; and the Seaside Convalescent Hospital.

The mortality last week was at the rate of 26 per 1,000 of the population in London, 27 in Edinburgh and Glasgow, and 28 in Dublin. Birmingham and Manchester showed the highest rate with 32 and 33 respectively, whilst Portsmouth was in the most favoured position of all the large towns in the United Kingdom, giving a death-rate of only 18 per 1,000 of the population.

We are pleased to observe that the registered mortality of Dublin has dropped down, for the week ending December 22, to 27·6 per 1,000 of the population—a fall of 10·0 per 1,000 below its highest point. The improvement is too sudden, we fear, to be permanent, but still the rate is higher than that of many of the large English towns. The deaths from zymotics have risen during the week from 30·4 to 37 per cent. of all the deaths, 4 of them being from small-pox.

There were 31 deaths from small-pox last week in London. None were reported from any other part of the kingdom. The deaths from the seven principal zymotic diseases in London last week were 301, being 27 above the corrected average, chiefly due to the prevalence of whooping-cough.

Dr. R. T. Harvey, Assistant-Physician to the House of Industry Hospitals, and Lecturer on Anatomy and Physiology in the Carmichael School of Medicine, has been appointed Pathologist to the Coombe Lying-in Hospital.

Dr. M'Gregor Croft, late staff-surgeon H. M. Army, has been chosen as Guardian Inspector of Hanwell, Colney Hatch, and Banstead Lunatic Asylums; also of the Asylums for Imbeciles at Leavesden, Caterham and Clapton.

THE MANCHESTER WATER-WORKS SCHEME.—THE DUTY OF MEDICAL MEN IN RESPECT TO IT.

The Lake district is, and should be, a source of pride to every Englishman. Switzerland, Ireland, Scotland, and other countries can boast of lake and mountain scenery, excellent of their kind, varying in degree of beauty and grandeur. Without invidious comparison or detracting from their merits, we may claim for the English lakes a strong individuality. Nature has, within a small extent of country, lavishly and profusely exercised her powers, and condensed into a compass—almost miniature—all those charms which delight lovers of the beautiful and sublime, affording subjects for the pencil of the artist and the pen of the poet.

The lake district is the national property of the people of England. It is the bounteous gift of Providence to them, all the more valuable in the present day for its rarity and its unique features. We know the value set on parks when in the neighbourhood of large towns. They are places for recreation, where our working classes can secure diversity of occupation, and pleasure, from the artificial imitation of nature's handiwork, in the terraces, vistas, arrangements of flowers, shrubs and trees, artificial lakes, and those other surprises which the landscape gardener so well contrives. But a still greater value should be set upon a succession of parks, fresh from Nature's hand, not the property of one town, but where every man can resort for change of scene, for the invigoration, in pure air, of his overtasked energies; where the hardy son of toil and the fortunate possessor of wealth can extract equal pleasure, equal enjoyment, equal benefit from the contemplation of scenery unrivalled in its class.

Independent of its physical and natural charms, the lake poets have filled the atmosphere of the locality with their influence, and the associations in connection with the district are rich in historic interest, so that every lover of Nature and every admirer of the school of Wordsworth must have a reverence for this garden of England. We hardly believe we have yet arrived at such a state of progress, that we can only regard as the greatest good, multiplied or quadrupled numbers of mill chimneys, multiplied factory operatives, multiplied misery, disease, and death for the dwellers in monster cities, and multiplied wealth in the hands of a few. The greatest happiness of the smallest number is not yet the guiding principle; the heart of the whole nation has not become so concentrated upon wealth and money, that everything has to be utilised for the benefit of the enterprising speculator and trader. There yet exists a love of nature and sentiment, without which life would hardly be worth living for, and this love of Nature is not alone confined to the educated or upper classes, but permeates through all ranks of society. Of this we have convincing proof, when we see the avidity and eagerness with which the Londoner, after his week's work, repairs to our public parks and suburbs; in the number of naturalists, geologists, and botanists, we know exist in all large towns, and in every part of England medical men must have noticed the pure, genuine love of the country, possessed by nearly all Englishmen.

Though we knew the spirit of the age was inclined to utilitarianism, yet we never deemed it possible that a scheme would be introduced to destroy the beauty of the fairest portion of England. This scheme is all the more monstrous as it is not a national one. It is a selfish, sordid, local speculation, and we feel sure, when the people are fully informed of its character and consequences, they will resist to the utmost of their power such an invasion and usurpation of their rights.

Manchester has decided to apply to Parliament in the session of 1878 for power to convert one of the most beautiful of our English lakes into a reservoir, so that the corporation may sell the water to neighbouring towns, and thus realise a handsome profit, to the relief of their local taxation. If Manchester required *water for health purposes* no objection could be raised, as the wants of man stand paramount to all other considerations, but such is not the case; there is an ample supply for health purposes, and this attempt to secure for a particular locality and for a small portion of the community, benefits, at the expense of the interests of the whole country, should be resisted, as a matter of principle and duty.

We have looked at the question from its sanitary side, as it affects the toiling millions of our great cities, for whom we must preserve some part of England, where they can escape from man's work, and from the incessant din, and turmoil, and polluted atmospheres of our large towns and cities. Pure water is, we know, an essential, but Manchester is not suffering from a dearth of water, nor is there any danger in the future of such a calamity. She has other sources of supply, as our contemporary, the *British Architect and Northern Engineer* points out, as accessible, more abundant, preferred by its engineer, with water as pure, pressure as great, or greater, in every way as suitable, and which Manchester can obtain by improv-

ing the country or district where it may be had. Pure air, delightful scenery, the preservation of one district in its primitive state of nature, are as necessary for the preservation of health as water supply, and when we put in the balance the Imperial interests of the whole country on its sanitary side, with the local and commercial interests of one town, there can be no question which should be preferred. We are convinced Manchester has not shown a case, and we must ask the profession to support the Thirlmere Defence Association, which numbers on its committee such men as Thomas Carlyle, Professors Seeley, Adams, Clark, Ruskin, and Knight, the Right Rev. the Lord Bishop of Carlisle, the Earls of Bradford and Bective, and other names well known, high in the social, as well as in the scientific and literary worlds. The committee have published full particulars of their claims to a hearing, and we can heartily lend them our support, and agree with their very moderate request. The Secretary to the committee, Mr. Robert Somervell, Hazelthwaite, Windermere, will furnish statistics and public proofs of the unjust and injurious nature of the proposed undertaking, which, if carried out, will be nothing less than a national blot upon England's beauty. He will also supply petition-sheets for those anxious to assist, by obtaining signatures for presentation to Parliament, and last, though not least, he will be glad to acknowledge the receipt of any sums towards the heavy expenses necessary for exposing the Manchester scheme. It is a question between the monied interest,—between speculators and the overworked classes, who love, not only the Beautiful and the True, but who value health and health-resorts.

Correspondence.

RESULTS OF THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last week's number I observe two more letters, one from Dr. Birkbeck Nevins, of Liverpool, and one from Mr. Caruthers, of Kegworth, criticising my remarks on the operation of the Contagious Diseases Acts, to which I must ask you to allow me an opportunity to reply.

Dr. Nevins objects to my statement that primary venereal sores have been reduced by more than one-half in the protected stations in the army, and that this is to be attributed entirely to the Acts. He says, "the army report for 1873 shows that they fell from 140 to 107 before there were any Acts whatever, and that during the years the Acts have been in the most complete operation, primary sores have only fallen at the protected stations at the rate of 6 per cent. yearly, instead of 9 per cent. yearly, which was the rate when there were no Acts." I have not verified these percentages, but admitting them to be correct, I deny that they have any real relevancy. What is the value as against the Acts, and where is the fairness, of a statement that the reduction per cent. per annum was not maintained at the protected stations at precisely the same rate as was observed for all the stations during the four years before the Acts, when no mention whatever is made of the fact that at the unprotected stations not only was this percentage of reduction not maintained, but a considerable percentage of increase took its place? It is only an ingenious mode of avoiding the main issue, which is whether there has been any marked diminution of disease at the protected stations when compared *for like periods* with the unprotected.

The argument that disease was steadily diminishing from independent causes has long been a favourite one with the opponents of the Acts, and this is not the first time it has been advanced by Dr. Nevins. Its fallacy was fully demonstrated in 1874, by Dr. Parkes, (*a*) who clearly pointed out its real cause, as shown by the yearly Army Medical Reports. In 1860 the number of troops in the United Kingdom was 83,386, and this was reduced between 1860 and 1866 to 59,758. During this time recruiting was almost in abeyance, bad characters were got rid of as far as possible, and the steadier men retained. Coincidently, the ratio of primary sores fell from 130 to 78 per 1,000. In 1866 the numbers were again increased, recruiting became active, and the force was gradually raised from 55,758 in 1866 to 85,722 in 1872. There was, therefore, as might have been expected, a considerable increase of disease in 1867 and 1868, which was not counteracted by the Act of 1866, for it had not yet been brought into efficient working order. But this increase was not maintained; on the contrary, by 1872 the ratio per 1,000 *for the whole force* was reduced to 68·9. Now if this reduction were due to any cause other than the Acts, it should have been tolerably uniform at all the stations, whether under the Acts or not. It is important, therefore, to note the contrast. Comparing the 14 stations under the Acts with 14 stations not under the Acts at which the force was 500 men and upwards, the result was a fall at the protected stations from 87 per 1,000 in 1866 to an average of 52 per 1,000 for the 4 years 1870-73; while there was a rise at the unprotected stations from 79 per 1,000 in 1866 to 108 per 1,000 for the same 4 years. (*a*) Therefore the decrease on the whole force was entirely owing to the decrease at the protected, and in spite of the increase at the unprotected stations. The theory that the reduction was due to independent causes is therefore absolutely untenable.

Since 1873 there has been a great reduction at both sets of stations, owing, probably, to concealment of disease arising from an order stopping the men's pay while in hospital for these complaints. But the relative proportion is the same, the rates for 1876 being 33 per 1,000 at the protected, and 82 at the unprotected stations.

It is only by comparing large numbers and by taking the average of several years, so as to counteract casual fluctuations, that any reliable data can be obtained. In the face of the contrast which I have pointed out, it is idle for Dr. Nevins to publish the long statistical table which forms part of his letter, to show the separate ratios at 28 stations, 14 of which were under and 14 not under the Acts, and to suppose that he proves anything by pointing out that the two highest and two lowest ratios were at stations not under the Acts, and that there is a wide difference in both classes between the ratios at the different stations. Tables comparing one station with another, irrespective of size and other attendant circumstances, look imposing on paper, and are admirably adapted to throw dust in the eyes of careless or unreflecting readers, but when examined into they are obviously fallacious, and in no way invalidate the aggregate result.

With reference to the navy, Dr. Nevins comments on the Parliamentary return moved for by Sir Harcourt Johnstone in July 1877, and recently published. This return shows the number of cases of venereal diseases in ships stationed at 5 ports under the Acts, and of ships stationed at 5 ports not under the Acts, from 1860 to 1875, with the ratios per 1,000, &c.

From this return Dr. Nevins has "compiled" two statistical tables comparing the ratios of disease in different ships at different stations, or of one ship before the Acts with another ship after the Acts, but without noticing their complement of men or anything else connected with them; and he thinks he advances his case by showing that the ratios "vary from nothing per 1,000 to several hundreds, whether the ships were under the Acts or not."

It is unnecessary to examine these tables in detail; whether correctly calculated or not, they are in their essence fallacious, and nothing relevant can possibly be proved from them either one way or another.

The real point of issue rests upon a comparison of the aggregate results obtained at the two groups of stations. This is made perfectly clear in the return, and the only effect of these tables is to mystify the question by enveloping it in a dense cloud of figures.

Dr. Nevins says, with reference to the general results, "the navy report shows that in the five ports under the Acts venereal diseases fell from 101·53 to 77 per 1,000 *before* the Acts, and have risen from 77 to 106·66 per 1,000 since they have been in force."

This is only so far true that by adding syphilis and gonorrhœa together, the result for the years 1860-63, *before* the Acts, is a ratio of 101·53, and for the years 1871-75, *under* the Acts, it is 106·65; but the return does not show that it ever fell before the Acts to 77. It states that the

(*a*) See *British Med. Journal*, Dec. 19, 1874.

(*a*) See "Parliamentary Return," 1875, No. 265.

rate for 1864-5, under the Act of 1864, was 101·49, and that for the years 1866-70 it was 75·42.

What, then, is the real meaning of the aggregate increase of 5·12 per 1,000 between the first and last period? Dr. Nevins only arrives at it by adding syphilis and gonorrhœa together, although they are carefully separated in the return. It was necessary for him to do this, in order to avail himself of the great increase in the number of gonorrhœal cases latterly recorded—an increase from 26·51 to 63·08, while he suppresses altogether the explanation of this *apparent* increase, which is given by the Director-General, Sir Alexander Armstong, on the very same page of the return from which Dr. Nevins takes his figures, and which is as follows :—

"Previous to the passing of the Contagious Diseases Acts it was not the practice of the navy to place cases of gonorrhœa upon the sick list; thus, the majority of the cases were not recorded. Since the passing of the Acts the attention of the medical officers has been more closely directed to venereal diseases, and a large number of cases of gonorrhœa have been brought under their notice which would otherwise not have been seen. The apparent increase of gonorrhœa, which, it may be remarked, has taken place at all the stations, whether under the Acts or not, may be attributed to the greater number of cases recorded, rather than to any real increase of disease." (See p. 15).

I never expected any very marked diminution in the frequency of gonorrhœa; though I am pleased to see that the recent army returns show a very considerable improvement, and no reasonable person will believe that the great increase of that disease which has been *recorded* in the navy can have been *caused* by the careful seclusion in hospital of all prostitutes found to be suffering from purulent vaginal discharge.

But though availing himself fully of the increase of gonorrhœa, Dr. Nevins does not think it necessary to take any notice of the great diminution of syphilis shown in the return. It would not suit his argument to do so. This is, nevertheless, by far the most important part of the question, and the figures relating to it must have been staring him in the face at the time he wrote. I will, therefore, supply the omission by briefly pointing out the leading facts.

In the years 1860-63, before any Acts were passed, the ratio of syphilis was 75 per 1,000 (omitting decimals) at the five ports since placed under the Acts, and 70 per 1,000 at the five ports not placed under the Acts.

In the years 1871-75, with the Acts in full operation, the ratio was 43 per 1,000 at the protected, and 96 per 1,000 at the unprotected ports. There was, therefore, a fall of 32 per 1,000 at the protected, coincident with a rise of 26 per 1,000 at the unprotected; so that latterly the amount of syphilis at the former has been considerably less than half of that recorded at the latter. Surely, it is futile to argue that the Acts have nothing to do with the production of this very striking result.

If any of your readers will take the trouble to compare the plain and intelligible statements in the Parliamentary return with the complicated jumble of figures "compiled" out of them and published in your journal of last week, they will be enabled to form their own opinion of the candour and fairness with which the question of the Contagious Diseases Acts is treated by Dr. Birkbeck Nevins.

Your other correspondent, Mr. Caruthers, tells us that he has been studying the Contagious Diseases Acts under the auspices of Dr. Bell Taylor, of Nottingham, who is one of the most inveterate opponents of these Acts. It is not surprising, therefore, that his views should be somewhat one-sided in character.

I am not concerned with his vulgar abuse of those whom, on mere hearsay, he chooses to call "the low vulgar executives who are engaged in carrying out these obscene laws in our garrison towns." It is in the style which the agitation against the Acts has made familiar. There is, however, one point in his letter which I shall be glad, if you will allow me, to notice. Mr. Caruthers quotes the evidence given by me twelve years ago before the Admiralty Venereal Commission, when I said "the best way of diminishing disease would be to establish lock hospitals; much more good would be done by lock hospitals than by police regulations—voluntary hospitals would reach all who disseminate disease, whereas, the police would reach very few." I must have seen this answer of mine in print at least a dozen times in publications issued by the opponents of the Acts, but they have never, so far as I know, done me the honour to quote any of the evidence which Igave before the Royal Commission in 1873.

In 1865 I had had no experience of what might be done by proper regulations, and I did not then anticipate that a well considered measure, like the Act of 1866, was at all likely to be introduced. All I then knew was derived from a few months' experience of the Act of 1864, under which patients were received in the London Lock Hospital, and I had good reason to believe that very few of those who were actively disseminating disease would be reached by it, for the majority admitted were broken-down prostitutes with inveterate venereal disease, who must otherwise have become inmates of a workhouse infirmary.

Since then I have had a large experience of the Acts of 1866 and 1869, under which all known prostitutes are periodically examined, and *all* who are diseased are effectually reached. I could not have believed, had I not witnessed it, how great a change can be brought about in the condition of women of this class under the influence of regular inspection and early treatment. In the Government wards of the Lock Hospital, phagedæna is almost unknown, suppurating buboes are rare, primary sores are, for the most part, mild, and even secondary affections have shared in this general change for the better. In all these respects the contrast between the patients under the Acts and those in the voluntary wards is most striking.

From what I have thus seen I have come to the conclusion that voluntary lock hospitals will always have the radical defect that women of the prostitute class will not apply for admission until the aggravation of their disease compels them to do so; in its early stage they will widely propagate contagion. Besides this, a large proportion will insist on leaving hospital before their cure is complete. For these reasons the voluntary system can never be effectual in mitigating the prevalence of venereal disease, the women will not come in soon enough, and will not stay in long enough. These defects are avoided under a system, such as that of the Contagious Diseases Acts, the essence of which is periodical examination, early treatment, and compulsory detention; and it would be a great sanitary advantage if it could be applied to all large centres of population. It is required for the protection of the public, which numbers so many innnocent victims, while it would at the same time protect the women from themselves, and save them from all the lamentable consequences of neglect.

Your obedient servant,

Dec., 1877. JAMES R. LANE.

NOTICES TO CORRESPONDENTS.

SPECIAL NOTICE.—In our present Number we have given eight pages extra, so that the half-yearly Index may not take from the ordinary number of pages of matter. Correspondents who do not find their communications inserted or referred to will please attribute the omissions to want of space. We have at least a hundred columns of matter waiting insertion, and if our friends will kindly bear our difficulties in mind, they will, we are sure, confine their communications to the shortest space consistent with perspicuity. A little forbearance also on the part of those who have complained of the delay in the insertion of their papers will greatly assist us.

AN IMPOSTURE.—We desire to caution our readers against a firm of advertisers, styled Bentley, Kemp, & Co., of 325 Broad Street, Birmingham, whose announcement appeared in our last number, also in other medical and lay journals. Upon receiving the said advertisement in the ordinary way, our Publisher had no suspicion that it was not of a perfectly *bonâ fide* character, especially as the advertisement has already appeared in the *Lancet*. Having since ascertained that Bentley, Kemp, & Co. are swindlers, and that one of them is already under arrest, and his confederates subject to the careful attentions of the police, he is anxious that our readers should be put on their guard against sending money to the said firm, and desires at the same time to express his regret if the appearance of the advertisement in our columns has caused any one the annoyance of finding himself the victim of misplaced confidence.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 2.)

Case VII.—*Syphiloma involving the Cortex of the Superior and Middle Frontal Convolutions of the Left Hemisphere—Alternate Pseudo-hemiplegia, first of Left and then of Right side (cross Paralysis, but not due to Disease of the Crura or Pons Varolii)—Hallucinations, &c.—Dementia.*

This case has some important points about it, and is well worth recording. It shows clearly the migratory and stealthy action of syphilitic changes, subtle in their development, and erratic in their mode of procedure. It was evident that a growth existed, or that pressure was exercised in the *left* cerebral hemisphere, yet it was followed by a *left* hemiplegia. This would accord very nearly with Dr. Brown-Séquard's recently attempted demonstrations, and I must say that in this case, although absolutely in opposition to my usual experience, I am inclined to the belief that this patient had a paralysis on the same side of the body as the brain lesion, and which was due to it, and I regret that my practice in cerebral physiology and pathology has not been so extensive as to allow me to clear up the following question with anything like definition; namely: Has the periphery of the cortex, which covers certain convolutions conducting fibres which do not enter into the decussation at the anterior pyramids, but travel along independently of them, and by an ndirect channel. I have for a long time, from clinical experience alone, entertained such a view, but I have great pleasure in stating here that both my knowledge and belief are in direct contradiction to those who maintain that a complete paralysis of one half of the body can result from a gross lesion (hæmorrhage, for example,) of the centrum ovale or of the mass of a convolution of the motor centres or tracts in the brain of the same side of the body. Yet I shall detail a few cases where there has been slight peripheral cortical compression (not irritation), which has given rise to an ill-defined paralysis of the extremities on the same side.

M. W., æt. 60, admitted Nov. 10th, and died in the month of May following. A strongly-built woman. She admitted that when between forty and fifty she contracted the disease, and that she suffered from sore throat, but quite recovered, and had good health until a month previous to her coming under my care. About this time she wanted proper food, became much reduced in health, and had an attack of what she termed erysipelas, which was soon succeeded by violent neuralgic pains over the *left* half of scalp, face, neck, and upper extremity (nothing relieved these pains like a hot solution of chloral). The whole of the *left* half of the forehead was considerably enlarged, extremely painful and boggy, which was attributed to inflammation of the periosteum and the bone. There was no objective paralysis, excepting that the *left* arm felt heavy and was not so responsive to voluntary movements as the *right*.

The countenance was dull, heavy, and dejected, her memory failed as well as reasoning power, and she talked of doing the most improbable things. It was two months after she came under my care that the paralysis became evident, yet a weakness of the left limbs had been gradually coming on. When she was getting out of bed on Feb. 4th, 1875, she found that she was unable to use either the *left* leg or *left* arm, but power to move them was by no means absolutely lost, and sensation was little affected. It is interesting to note that from this time the acute pain in the head gradually became of a dull aching character, and then permanently ceased. When spoken to about herself, she complained of having an empty space in the left side.

On April 10th, it was noted that there was marked right facial and general paralysis of the *right* half of the body. The paralysis of the *left* side had now passed off,

leaving an intense hyperalgia. Urine was acid, gravity 1012, no albumen.

On April 30th she was much weaker in every way, although she possessed voluntary power over all the limbs. The speech was unaffected, no control over sphincter. The temperature of the two sides of the body is now about equal, but the *left* at one time exceeded the *right* by more than two degrees. There were neither convulsive movements, tremors, or contractions from first to last. She died from exhaustive diarrhœa.

Post-mortem Examination.—Upon removing the scalp, the frontal bone was found to be devoid of periosteum and carious. The same condition was observed of the internal table.

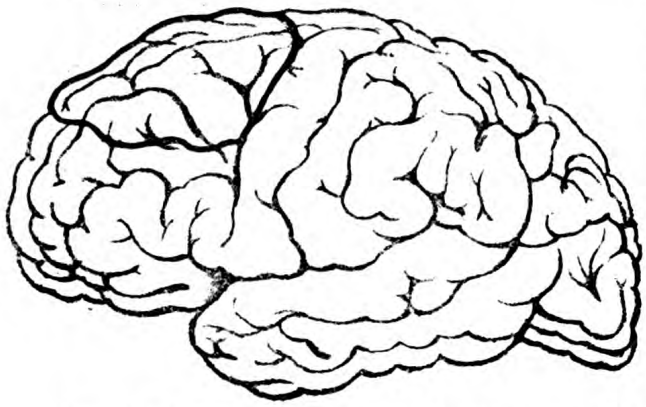

FIG. 2.—Showing outline of growth of convolutions of left anterior lobe.

The dura mater was adherent to the skull over the *left* anterior lobe, where it presented a yellowish appearance and was much thickened. It was also firmly adherent to the first and second frontal convolutions of the *left* side (as shown in fig. 2). Upon making a section through the grey matter of these convolutions, it was seen to be almost entirely replaced by the growth which had evidently taken its origin in the endosteal layer of the cranium, the surrounding substance was purplish in colour, and softening, although not advanced, had commenced.

There was general opacity of the arachnoid over the hemisphere, with a considerable amount of fluid, and the vessels at the base were atheromatous. The brain substance otherwise was quite normal in appearance.

The capsule of the liver towards the free border of the lobes was thickened and opaque. There was evident sclerosis of the visceral parenchyma.

If clinical and pathological deduction in reference to the motor and physiological functions of the brain are of the value which I have always supposed them to be, this case must stand prominently forward as an example, and also as a proof of the value of experimental research, because we have here a slowly growing tumour gradually giving rise to an objective paralysis according to the brain substance invaded.

We know that the anterior lobes as well as the anterior portion of the frontal convolution are without the domain of the recognised motor area, but within that of intelligence. The growth took a course upwards and backwards, involving the anterior part of the anterior central convolution, and to it succeeded the *right* hemiplegia, but no aphasia. And for what reason? Because the third inferior frontal convolution was in no way implicated. To say the least, this isnegative evidence in favour of M. Broca's well-ascertained facts, that the speech centre is in the third *left* frontal convolution.

CASE 8.—*Progressive Right Hemiplegia—Right Facial Palsy—Very sensible Atrophy of the Muscles of the Upper Extremity and Thorax, with Muscular Fibrillations on the Right Side—Hemikinesis with marked Muscular Hypertrophy of the Muscles of the Extremities and the trunk of the Left Side.—Atrophy of the Muscles of the left half of Tongue, the Pillar of the Fauces, and Vocal Muscles of this, the Left Side.*

J. C., æt. 29, by occupation a lawyer's clerk. His health was excellent until about five years before he came under my care. There was no history of either paralysis or fits in the family. At the age of 24 he not only contracted syphilis, but became gay and dissolute in his habits; and four years after he experienced a want of normal power over the right arm, which increased gradually, so that this extremity was almost powerless before the right leg became affected, six months after.

When I first saw him the following notes were made. Is lying upon his back, quite helpless and unable to perform one single movement co-ordinately; his reason is only to a slight extent impaired, but it cannot be defined with anything like precision.

Beginning with the cranial nerves, we find: 1. The sense of smell to be normal. 2. Sight good, no diplopia, ophthalmoscope shows an atrophic change around the margin of left disc. 3. Ptosis of left and right eye-lid, very marked of the former, but slight of the latter, and a similar state exists in reference to a divergent squint. The muscles of the left eye were generally less co-ordinate than those of the right, the left pupil being more contracted. 4, 5. The motor branch of the fifth nerve is only slightly involved, neither is sensation to any great extent. 6, 7. There is marked palsy of *right* facial muscles, rather more pronounced than that usually attendant upon convolutional disease of the opposite hemisphere. The auditory nerve is affected on the *left* side, where, be it remembered, the third nerve is chiefly involved, and not at all on the *right*, where the facial palsy exists. 8. The glosso-pharyngeal nerve is decidedly involved upon the *left* side. But the fauces generally are devoid of common sensation and reflex excito-motion. The left palato-glossus and palato-pharyngeus act very imperfectly, and form a kind of curtain on this side. The *left* vocal cord does not act so freely as the *right*. Respiration and deglutition are affected. At times the breathing becomes hurried and almost panting, and the act of swallowing is considerably interfered with from involvement of the pharyngeal plexus. 9. It is somewhat interesting to note how far the hypo-glossal nerve is affected; I mean whether it is indirectly or partially involved at its centre of origin. The tongue is protruded and pushed well over to the *right* side, but its *left* half has undergone considerable *atrophy*. This is in striking contrast with the muscles of the *left* half of the body, which we have noted to be considerably hypertrophied. The speech is drawling and jactatory. There is no aphasia. Of the *right* extremities, the arm is completely powerless, he cannot even move the fingers but sensation is only slightly affected. Electro-muscular contractility is increased. The muscles of the trunk on this side are in like manner atrophied, both those of the thorax and the abdomen. The *right* leg is in the same state of paralysis as the arm, but the former is rigidly extended, while the latter is flexed and the fingers well contracted into the palm. Electro-muscular contractility normal. The *left* half of the trunk and *left* extremities present a marked contrast to the *right;* for instead of the shrunken, passive, immovable limbs, they are seen to be greatly increased in size, the muscles standing out in bold relief, and far beyond their normal development; they are in a state of continuous passive movement, which simulates that of chorea more than the spasmodic jerkings as described by Saltorini, or those which have been noticed by some other observers under the name of athetosis. Rest of posture does not alter them, but they cease during sleep. Now and again he has controlling, but not co-ordinating, power over them, and like other inco-ordinate muscular spasms, they are always increased when ideation is brought to bear upon voluntary motor acts; even the effort to speak increases their force considerably. It is interesting to compare also the intrinsic muscular fibrillations of the *right* half of the body with the gliding snake-like muscular

movements of the *left* half of the body, each condition having its physiological and pathological significance. He often complains of severe nocturnal pain over the *left* brow, as well as in the tempero-sphenoidal regions.

From these signs it was inferred that he was suffering from a cerebral growth, which, from the history, was considered to be of a syphilitic character, and that in all probability it existed in the left half of the pons varolli, and left half of the fourth ventricle involving by degenerative change the optic and striate bodies, internal capsule, and *right* half of the pons and crus.

Antisyphilitic remedies were tried for nearly six months, and with some good result; he regained some power in the *right* leg, and the movements of the *left* arm decreased, so that he could carry a cup to his mouth, and sensation became normal all over the body.

Beyond this, however, he never got better, and on the day of his death the following note was made:—

Has been gradually losing power for the past six months, but for the past fortnight he has become so weak that the voice was scarcely audible, and swallowing extremely difficult. Sphincters incompetent, bed sores upon buttocks, no convulsions, no loss of consciousness until within an hour of his death. For some time he has suffered from attacks of prostration, difficult breathing, partially stertorous, with profuse sweating and flushing upon the *right* half of the forehead and face, divergent squint and complete ptosis of the left eye. In all other respects his physical condition, up to the time of his death, corresponded to the notes previously made.

The inability to obtain a *post-mortem* examination in this case is greatly to be deplored, as in its clinical and other aspects it presented a series of phenomena of unusual interest and scientific and pathological importance.

Hornsey Lane, N.

(To be continued.)

TRACHEOTOMY IN DIPHTHERIA. (*a*)

By W. H. QUILL, M.D.,
Surgeon, A. M. D.

My reason for drawing attention to this debateable subject is, the strong conviction I have of its *importance*, combined with the pleasing fact of my being able to detail a successful case, the happy result of which will, I trust, help in strengthening the opinion of those who advocate the justifiableness of the operation in the disease in question upon the advent of the symptoms of threatened asphyxia.

It will readily be granted me that the subject is one of no mean importance, involving, as it obviously does, an attempt to elucidate the best means of snatching from the jaws of a most painful death a human life; consequently, I feel it to be incumbent upon all who have the power, to help in throwing light upon the question, so that we may, on the one hand, not unnecessarily betake ourselves to a serious operation; *nor*, on the other hand, allow an ill-founded diffidence as to the benefit likely to be derived from the operation, to deter us from operating once we are satisfied of the evident failure of medicinal measures in checking the fatal progress of the disease.

Without further preamble, I will now detail the following case in point, and afterwards will append to it such general observations as may appear to me requisite and instructive.

On the 12th June, 1876, while in medical charge of the 17th Lancers, I was asked by one of the officers of that regiment to see his child (a boy aged 5½ years), who was supposed to have a *sore throat*.

At my visit, I found the child to be suffering from what was, to all appearances, a severe attack of *Tonsillitis*. Both tonsils were much enlarged, almost meeting in the middle line; at this period of the case there was not the slightest appearance of false membrane, nor was respiration interfered with in any way, and in point of fact, the child felt so well that his parents found it a difficult matter to keep him within doors, more especially as he was by nature headstrong and obstinate.

My recommendations were that the boy should be at once put to bed and kept there; that hot linseed meal poultices should be kept constantly applied round his throat; and in addition prescribed a few grains of calomel and James's powders, to act on his bowels and skin; diet to consist of liquid nourishment, such as milk, chicken-broth, beef-tea, &c.

Before going further in the case, I should like here to interpolate that I had no grounds for supposing that my case would possibly turn out something more serious than the trifling tonsillar affection; there were at the time no cases of diphtheria or other throat affection in barracks, nor *had* there been any, so far as I knew.

Apologising for this digression, which, however, I think was necessary, I will now proceed with my notes of the case:—

On the 13th inst (*i.e.*, the next day), there was no appreciable change for better or worse in the progress of the case; but on the following day, the 14th inst, there was, for the first time, *slight dyspnœa*. On examination of the throat, I found nothing to account for this symptom, except the excessive tumefaction of the tonsils, which now so completely blocked up the faucial passage that it was impossible to see the condition of the pharynx. There was no cough, and the nourishment ordered was taken without much difficulty.

June 15th.—The dyspnœa was found to be much increased this morning; the respiration being in fact *stridulous*, leaving no doubt in my mind of the inflammation having extended to the larynx.

Examination of the throat (which was effected with great difficulty) revealed that the still tumid tonsils were now spotted here and there with whitish patches. I lost no time in seeing my friend Surgeon-Major Johnston in consultation, who agreed with me as to the serious nature of the case, and in the necessity that existed for the employment of more active treatment than had hitherto been adopted, owing to the case having been apparently "tonsillitis," an affection requiring time and nursing more than medicine for its removal.

The treatment decided on was, the constant inhalation of steam, by means of a special apparatus; the alternation of hot stupes and hot linseed meal poultices to the throat; the application to the tonsils and larynx of a very strong solution of nitrate of silver; and, looking to the lusty, plethoric child we had to deal with, we thought it judicious to prescribe the administration of ¼ of a grain of tartar emetic every third hour, until nausea was produced.

We also recommended that the child should be placed in a *hot bath*, whenever a dyspnœic paroxysm of more than ordinary severity occurred.

16th.—The treatment employed failed to exercise any check on the progress of the disease, the child being, on the contrary, considerably *worse;* (*a*) for now the face was somewhat congested; (*b*) the air was drawn into the lungs with an intensely stridulous sound; and (*c*) the paroxysms of dyspnœa were steadily increasing in length and severity.

Under these circumstances, we had the advantage of bringing to our councils Dr. Banks; and careful consideration unanimously decided—the child's parents not objecting—on the necessity that existed for the immediate performance of tracheotomy.

No time was lost in proceeding to operate, but before any step in the matter could be taken, a fearful paroxysm of dyspnœa came on, during which the face and lips became completely livid, the eyes protruded, respiration ceased, the child became insensible, and was, apparently, dead. At this anxious movement, Dr. Johnston (with the assistance of Dr. Banks and myself), opened the

(*a*) Paper read before the Surgical Society of Ireland, Dec. 7th, 1877. The discussion will be found on page 27.

trachea (the child being quite unconscious to the proceeding); immediately out rushed with great violence the pent up air, bearing with it a quantity of bloody mucus, and several unmistakable pieces of diphtheritic false membrane.

The change which now took place in the child's appearance was something marvellous; the livid purplish aspect of the face gave place, like magic, to the hue of returning life; with a long-drawn inspiration the child opened his eyes (which we all had feared were closed for ever), and gazed wildly about him, trying apparently to comprehend what had happened.

Without loss of time, the operation was completed by Obré's double tracheotomy tube being introduced into the trachea, and securely tied in there by tapes passing round the neck.

The child now breathed freely through the tube, and on being put to bed, almost immediately fell into a calm sleep.

18th.—Until the 18th of June, *i.e.*, the second day after the operation, the progress of the case was in every respect most satisfactory. On that day, however, an alarming paroxysm of dyspnœa *suddenly* supervened, the child, in the space of a few seconds, becoming almost moribund. Dr. Johnston, most fortunately, happened to be present, and succeeded after a few anxious moments in freeing (by means of the feather end of a long quill pen), the obstructed tube; a violent expiration followed this manœuvre, during which "a perfect cast, in false membrane, of the lower portion of the trachea and upper portion of right bronchus was forcibly expelled," immediately upon which the dyspnœtic paroxysm ceased.

This cast of false membrane measured some four inches in length, but, I regret to say, it was not preserved. It was a most faithful model of the lower portion of the trachea and adjoining portion of right bronchus, and would, I think, convince the most sceptical of the diphtheritic nature of our patient's disease.

I will not, sir, take up your time by detailing the subsequent daily progress of the case, inasmuch as it was, so far as could be expected, in all respects satisfactory.

Nor will I relate in *extenso* the treatment carried out after the operation; it would be tedious my doing so; consequently, I will only say that the most assiduous care on our part was bestowed on it, *especially* in the matter of not admitting to the lungs any air before it was duly warmed, and the constant keeping of the tube sweet and clear.

The tube was removed on the evening of the 5th day after the operation, but had to be re-introduced on the following day, owing to a slight return of dyspnœa.

Having to accompany the 17th Lancers to England on the 23rd inst., Dr. Johnston kindly took charge of the case during my absence, and I am indebted to him for the notes of the further progress of the case to a happy termination.

25th.—On the 25th inst., difficulty of swallowing gradually came on, and increased to such a degree that the child had for several days to be nourished entirely by nutrient enemata.

28th.—The tube was finally removed to-day, without the respiration being in the least interfered with.

My note on the 10th July is:—

"The dysphagia has entirely ceased; the tracheal aperture has almost completely closed, articulation is rapidly become quite distinct, and the child's general health is excellent."

22nd.—On the 22nd July, the boy accompanied his parents to England quite convalescent, and is (so far as I know) at the present time perfectly well.

In recording the case just read, I must confess to a feeling of intense satisfaction at its happy result.

The facts of the case, accepted with all proper reserve, possess in my judgment a practical value which deserves to be earnestly enforced, inasmuch as they ought to help in dispelling the idea, far too prevalent I fear among our profession, "that tracheotomy must be looked upon as simply *palliative*, when false membranes have extended into the trachea."

Objections to the Operation.

On this point, I will with your permission, read the following extract from one of our most valued text books.

The author, while enumerating various objections to the operation of tracheotomy in diphtheria, says:—

"If the false membranes have extended *below* our incision, the operation being purely mechanical, can afford no relief, but may seriously add to the danger." (*a*) In answer to this statement, I would direct your attention to the three following points:—

1. That it seems to be a clinical fact that the existence of the disease (by which I mean the further formation of the false membrane), seems *to be arrested by the operation.* As I look upon this opinion as one of deep importance, I beg permission to quote the following passage from Trousseau's Clinical Lectures:—

"It is a remarkable fact (says Trousseau), that when once tracheotomy has been performed, there need no longer be entertained any anxiety regarding the diphtheritic manifestations of the pharynx and larynx, which formerly it was imperative to attack by very active measures; they disappear spontaneously. It appears that by the time the disease has reached the air-passages, it has exhausted itself; and that if by admitting air to the lungs, by tracheotomy, the patient be prevented from dying, recovery will take place."(*a*)

2. I would point out that the introduction of a large tube, close to the seat of the disease, enables the choking false membranes to be discharged with far greater facility than if they had to traverse the entire length of the trachea and larynx in the attainment of that object; moreover, the presence of an artificial opening in the trachea, through which respiration is carried on, gives "physiological rest to the larynx," a point of no mean value when we remember the important structures it contains, and the ill-effects that must result to them from the abnormal constant activity of the connecting muscular apparatus, and the frequent forcible contact of pellets of diphtheritic deposit.

Lastly, I would direct your attention to the case I have just read, in which beyond the possibility of doubt, false membranes *did* extend below our incision, notwithstanding which the operation not only afforded immediate relief, but was followed by complete recovery.

I do not intend attempting to answer all the objections that have been urged against the operation in question; many of them I look upon as frivolous, and my attempting to combat them would only be taking up your time and testing your patience unwarrantably. I will therefore content myself with criticising some of the objections advanced by the late Dr. Cheyne and the late Professor W. H. Porter, both distinguished authorities on the subject.

Dr. Churchill quotes Dr. Cheyne as remarking, "that in all cases *he* has observed there is a sufficient space for the passage of air to the lungs, and consequently that if the larynx be closed it must be by *spasm* in addition to exudation, and that therefore to attempt relief by a mechanical operation would be superfluous."

Much as I respect the opinion of this eminent physician, I cannot bring myself to acquiesce in the soundness of his conclusion. For argument's sake, we will suppose his data to be correct, *i.e.*, that the larynx is closed by *spasm* as well as by exudation: surely it would not follow from this, as a necessary sequence, that the *spasm* is propagated to the trachea, or that it would be on the introduction into it of a tube. Remembrance—

a. Of the greater comprehensive size of the trachea;

b. Its greater expansibility; and—

c. Its lack of what I may call spasmodically inclined muscles, might prevent such a conclusion being arrived at.

(*a*) "Diseasees of Children," by Dr. Churchill, page 344.
(*b*) Trousseau's Clinical Lectures, vol ii., page 607.

I would further say (and I do not think the remark to be far-fetched), "that I deem it by no means improbable that the presence of a small amount of false membrane in the larynx may produce fatal asphyxia, where a similar amount in the trachea would produce few, if any, serious symptoms." The possible truth of this conclusion will, I think, be apparent, on our remembering the various *obstacles* (so to speak) which exist in the narrow larynx; by *obstacles* I mean the vocal cords and various muscles which traverse it. Surely it is not improbable but that one or more of the powerful inspirations which are rapidly recurring may double back, and so entangle, as it were, on one or more of these *obstacles* loose flakes of false membrane, so that complete occlusion of the glottis results, and consequent death by asphyxia; but if in such a crisis we rapidly and skilfully introduce a tube into the trachea, the present imminent danger to life would be, I apprehend, safely tided over, at least for the time being, inasmuch as we have now respiration carried on through a larger tube, free from such natural obstacles as exist in the larynx, and consequently far less likely to be choked up by existing false membranes, an event rendered still less likely when we remember the lessened force of the inspirations, now carried on through the introduced canula.

Professor Porter says the great contra-indication to the operation is "the false membranes having extended below the larynx, and that as it is impossible to ascertain whether this be so or not, we should not attempt to operate except in very exceptional cases." In point of fact, he says we should only operate in such a case as this: "If the infant is (to all appearance) dead, and the surgeon is called to him within any reasonable time, he should then, with the least possible delay, open the trachea or larynx."

Regarding this summing up of Professor Porter's, I most sincerely trust no surgeon of the present day believes in the wisdom of it. I do not here combat the Professor's statement as to its being compulsory on us not to surgically interfere in any case unless we are certain the false membrane has not extended below the larynx, inasmuch as I have already replied to this objection.

Professor Porter, in his published writings, I find strongly opposing the justifiableness of the operation except in very exceptional cases, but I remember at the same that his opinion was written some forty years ago, at a time when there was not the same abundance of data for arriving at sound conclusion regarding the justifiableness or unjustifiableness of the operation as there is now; had the Professor's life been spared until the present time, I am convinced we should hear his voice advocating instead of condemning the operation.

An objection to the operation that Professor Porter lays *stress* on is the "uncertainty of the result." I do not for one moment attempt to deny the attendant uncertainty, which I fully acknowledge largely exists, but would, once and for all, bring out clearly before you this salient point.

That in all cases in which tracheotomy is indicated, death is, I may safely say, certain if the operation be not undertaken, while it by no means follows that such will be the result if the operation is carried out. No one can make such an assertion in the face of the many successful cases that have been from time to time recorded.

It seems to me, indeed, that those who, without any further reflection, allow themselves to be influenced against the operation by taking into account the large proportion of deaths which follow it, are apt to forget the fatal results which commonly follow all serious surgical procedures.

A correct Diagnosis important.

Though having no desire to discuss the vexed question of the identity or non-dentity of the diseases respectively termed (*a*) Diphtheria, and (*b*) Croup, I nevertheless am anxious to touch upon *two* points bearing some connection with this subject which I deem well worthy of notice.

a. One is the paramount importance of distinguishing between *Diphtheria* and *Stridulous Laryngitis*, or, as some prefer to call it, false croup.

To avoid being misunderstood, I would here say that I make no difference between diphtheria and the so-called false croup, inasmuch as I believe them to be one and the same affection, true croup being nothing more than diphtheritic laryngitis.

b. The other is the benefit which is likely to accrue to our patients by our adopting the belief "that diphtheria (though in some cases a constitutional malady from its commencement) is in most cases *primarily local*, and subsequently constitutional."

In regard to the first of these points, I would say that the importance of not confounding diphtheria and false croup (*i.e.*, stridulous laryngitis) lies in the fact "that the proper treatment of the one would be most injurious in the other, and *vice-versâ*."

False croup is only dangerous from its position, and requires for its removal active lowering measures; *but* in diphtheria we have, sooner or later (if the local manifestations have not been energetically attacked by proper applications), a powerfully depressing blood-poison, dangerous in itself quite irrespective of its local signs, and the fatality of which would be greatly increased by any lowering treatment.

Speculation on the second point I consider in no way less worthy your attention.

I am quite aware of the existence of much difference of opinion on the subject of the primary *local* or *constitutional* origin of diphtheria, but I am persuaded we shall be acting best for our patient's interest, as well as for our own reputation, by looking upon the disease as being "*primarily local and subsequently constitutional.*"

The outcome of such a belief would necessarily be a constant watch on our part to catch the disease at its commencement, and having done so, to use with vigour and intelligence some of the many powerful topical agents at our disposal. I feel sure by so acting we shall, in many instances, *cut short the disease*, while if we fail in doing so no harm results from our interference.

I would also mention another special benefit to be derived from the early topical treatment of diphtheria. I allude to the disinfection and destruction of the specific diphtheritic poison-virus, which the false membrane is universally allowed to contain, and the consequent lessened danger of communication of the disease to others, as well as propagation of the disease to the patient's larynx.

Tracheotomy advocated.

I will now state as my earnest conviction, that it is the imperative duty of the surgeon to betake himself without hesitation to tracheotomy in all cases of diphtheria, where assiduous, well-directed medical treatment is evidently failing to exercise a decided check on the progress of the disease, evidenced principally by the—

1. More or less lividity of the face; by—
2. The epigastrium being strongly and deeply depressed at each inspiration; and by—
3. The working of the nostrils.

I would further add, that I hold it to be incumbent upon the surgeon to perform the operation, even though the chance of ultimate recovery be *infinitesimal*. I am here alluding to those cases of so-called "bronchitic diphtheria," *i.e.*, where the bronchi are blocked up by the morbid deposit; for even in these dreadful cases more than one recovery has been recorded after false membranes, manifestly moulded to the bronchial tubes, have been ejected.

In these dreaded cases we may see our patient in a state of absolute frenzy, casting himself at one moment on to his mother's neck, at another on to the bed or floor, and clutching convulsively at his throat, in the vain effort to remove the cause of suffocation; the face is livid, froth issues from his mouth, and from his haggard, terror-stricken eyes shoots an appealing look for help which cannot but melt to softness the most marble of hearts. In such a pitiable case I am unable to understand how anyone deserving the name of surgeon could stand with folded arms, and see "the mortal coil shuffled off" in such dire distress; surely, even

if the only result of the operation was the *euthanasia*, it would be his duty to lessen the agonising death-throes of the writhing child by opening the trachea, and so admitting to the poisoned blood the air it so grievously required.

Respectiug the *operation* in the case which has been read to you, I may mention that no difficulty was experienced in its performance. The hæmorrhage was very trifling, owing, I apprehend, to the care taken in not wounding any of the numerous distended veins which lay in the line of incision. But on this portion of the case I will not dilate, as I am happy to see my friends Dr. Banks and Dr. Johnston present, who will, I am sure, with your permission, give full information on the operative procedures, and enrich the case by many practical remarks. I cannot, however, refrain from saying that I consider the successful issue of the case was in a large extent due to the admirable coolness and skill with which Dr. Johnston carried out the operation under circumstances which I can testify were most painful and trying.

Importance of After-treatment.

Before concluding this paper, I am desirous to touch on the "after-treatment of tracheotomy cases :"—While fully allowing the importance of the operation being performed with skilfulness, and more especially, with coolness, I am, nevertheless, convinced that a large portion of its ultimate success will depend upon the *after-management* of the case. This opinion is to a great extent borne out by a knowledge of the interesting fact that a large proportion of those who die after tracheotomy succumb, *not to the disease for which the operation was undertaken*, but to *bronchitis* or *pneumonia* developed after the operation. Now as these affections are in great part attributable to the admission to the lungs of air which has not received that degree of warmth which normally it would receive in its circuit through the nostrils, mouth, larynx, and trachea, I hold it to be a matter of the utmost importance that no air should be allowed access to the lungs before it has received the essential degree of warmth. I will not take up your time, sir, by pointing out how this may be accomplished, as the obvious steps to be taken will naturally suggest themselves, but will rest content in drawing attention to a point which I believe to almost equal in importance the keeping clear of the tube.

I will now close this paper by the following quotation (in which I heartily agree) from the writings of Trousseau, one who has done more than anyone I know of towards establishing the justifiableness of tracheotomy in diphtheria. (*a*)

"For my part (says Trousseau), I am quite determined not to allow myself to be discouraged, but to preach tracheotomy with the greater conviction in proportion as its success increases ; and did the proportion remain what it was ten years since, I should still proclaim the necessity for the operation, nor cease to say that it becomes a *duty*, a duty as imperative as the ligature of the carotid artery after a wound of that vessel, though death follows the operation as often certainly as recovery."

Before resuming my seat, I must most gratefully thank you all for the attention with which you have listened to my paper, on which I cordially invite discussion.

ON THE INJECTION OF HOT WATER INTO THE UTERUS IN CASES OF POST-PARTUM HÆMORRHAGE. (*b*)

By LOMBE ATTHILL, M.D.,
Master of the Rotunda Hospitals, Dublin.

Dr. Atthill first commented on the means ordinarily used for the control of *post-partum* hæmorrhage, namely, cold water, which he contended, while most efficient in those cases where the loss occurred rapidly, and in patients whose vital powers were not lowered by any cause, was insufficient and often positively injurious in women who were debilitated by disease or other depressing cause, this being the class amongst whom fatal cases most frequently occurred. Dr. Atthill gave the details of cases illustrating this.

He then referred to the fact that for some years past he had been in the habit of treating some forms of menorrhagia by the application to the spine of Chapman's Hot-Water Bags, and had obtained good results ; that therefore when he saw in the American journals reference to the treatment of *post-partum* hæmorrhage by the injection of hot water, he at once decided to put the treatment in practice, and test its value by personal experience. The first favourable case which occurred was that of a woman, æt. 33, admitted into the Rotunda Hospital on the 28th Nov., in labour of her fourteenth child. Profuse hæmorrhage set in immediately on the expulsion of the placenta ; this was checked by the application of cold to the vulva and the intra-uterine injection of cold water ; nevertheless the uterus would relax, and the hæmorrhage, though in the shape of a little trickling stream of blood, continued ; the patient was now almost pulseless, and the body cold. She was in this state when Dr. Atthill saw her ; he at once proceeded to inject hot water at the temperature of 110° into the uterus, taking care to pass the tube of the syringe well into the uterus ; the effect was instantaneous. The uterus contracted firmly, and did not again relax, the pulse returned to the wrist, and the patient expressed herself as feeling most comfortable. Another case occurred on the 30th Nov. In this case the hæmorrhage was at first mainly internal, there was no external loss, but three hours after delivery the patient complained of being very weak, and on removing the binder the uterus was found to be distended with blood. On using pressure, an enormous quantity of clots and fluid blood was expelled, and hæmorrhage continued, which the use of cold failed to stay entirely. When Dr. Atthill saw her she was very pale and faint, in fact in a condition of great danger. He proceeded promptly to inject the hot water, and in passing his fingers within the os uteri with the view of guiding the tube of the syringe into it, he detected the existence of a tumour, probably a fibroid, in the anterior wall of the uterus. Nevertheless, he proceeded with the hot water injection, and with the same good results, as in the former case ; the effect on the pulse was very marked, and the patient subsequently stated that at the moment of the injection she experienced great relief from very severe pain from which she had previously suffered.

Dr. Atthill, in conclusion, pointed out that hot water was, by the experience derived from these cases, proved to be a safe and efficient remedy in *post-partum* hæmorrhage ; and had the great advantage of being always at hand. It was not intended to supersede the use of cold, but to supplement it. Dr. Atthill further urged practitioners to give the method a fair trial, assuring them of its safety, and expressing his belief that it would be the means, if brought into general use, of saving many lives.

(*a*) Trousseau, "Archiv. Gen. de Méd. Mers." 1855, p. 259.
(*b*) Read before the Dublin Obstetrical Society, Dec. 9th, 1877.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

The second meeting of the Session 1877-78, was held on Friday evening, December 7th, 1877.

Dr. Robert McDonnell, F.R.S., President of the College, in the Chair.

VESICAL CALCULUS.

Mr. H. G. Croly exhibited a calculus of the mulberry variety, which he removed on Tuesday week last from a boy six years old, by the ordinary lateral operation. The stone was extremely rough, and produced great torture, the little boy suffering more than he had ever seen a patient suffer before.

OVARIAN TUMOUR.

Mr. W. I. WHEELER laid before the Society a solid ovarian tumour, developed in the right ovary and broad ligament. The patient stated that she was unmarried, and had never borne children. She was forty-five years of age, and had always enjoyed good health up to ten or eleven months ago, when she observed that her left side had gradually got larger. The catamenia now became irregular, and she then consulted Dr. Lyster, whose diagnosis was exactly the same as that made in hospital. Under the medical treatment she had in the country, the catamenia were for a time again produced, and became regular. The abdomen measured round the umbilicus fifty-two inches, and from the umbilicus to the right anterior superior spine, nine inches, and from the umbilicus to the left anterior superior spine, eight and-a-half inches. There was a considerable amount of resistance given on feeling the tumour. The integuments moved freely over the tumour, which appeared to be more prominent on the right side than on the left, and it was an interesting point that the patient always complained of having first felt the enlargement on the left side, and the pain entirely on the right side, although the tumour, as we afterwards found, and proved by examination before the operation, was one that must have originated in the right ovary and the right broad ligament. There was considerably more resistance on palpation in the right than in the left side; and on percussion in certain positions, there could be found a sense of fluctuation, while in others it was absent. On making a vaginal examination with the finger, it was found that the entire space known as Douglas's space, was fully occupied. On pressing the abdominal parietes with his finger in the vagina, a sense of movement was distinctly conveyed from one portion of the tumour to the other. On examining with the sound, the uterus was not found at all enlarged. As to length, it was normal; but the os uteri was rather larger than that of a woman who had not borne children, and when traction was made upwards towards the ensiform cartilage, the sound appeared to be drawn up, as if the tumour was attached to the uterus. A second examination, when the patient had been placed under chloroform, was made, with the assistance of Dr. Macan. There did not then appear to be the same amount of adhesions that were found before they placed her under the influence of ether, and on passing in the sound they were able to get the fingers directly round the fundus of the uterus, showing that there was no attachment whatever of the tumour to it. The fundus of the uterus was pushed over to the left side, evidently showing that the tumour was not originally growing from the left side. That day he had performed the operation in the City of Dublin Hospital. The patient was, as he had said, forty-five years of age. They found considerable adhesions. The reason that there was the idea of its implicating the place at which the tumour was attached, which could be seen, would almost give the idea of a fibrous tumour of the uterus, from the way in which he had taken it off, it showed so little of the pedicle. The tumour appeared to be a solid tumour of the ovary and broad ligament, and portions of it showed an increased development of the fibrous stroma of the ovary, that he believed had been described by many authors under the name of cystic sarcoma; but that it was not a pure fibrous tumour of the ovary was plain, for the reason, that they had found cysts in that tumour, and those cysts appeared to be blocked up or encroached upon by tissue, which was evidently an increased development of the fibrous stroma. In this portion of the tumour there was a little cyst, and the reason that some of the fluid did not flow, appeared to be because the trachea was blocked up by this fibrous matter. The tumour was ten pounds in weight, and at six o'clock that evening the patient's pulse was 80, and she was doing as well as could be expected. In conclusion he had to thank Dr. Kidd, who kindly examined the patient with Dr. Macan. Their opinion coincided with the diagnosis previously made, and with what was found after the operation.

ŒDEMA OF THE GLOTTIS.

Dr. THOMSON exhibited the larynx and part of the trachea of a man who died in the Richmond Hospital two or three nights ago. The history that he could give the Society of the case was a very bald one, from the circumstances that the man was admitted late at night, that they were able to get very few particulars, and that he died very shortly after his admission. So far as could be learned it appeared that the patient was at work on the day before and got a very severe wetting, and was complaining on that evening of some tenderness about the throat. Next morning, the morning of the day of his admission to hospital, he went to work as usual, but about mid-day his throat became so bad that he found it necessary to give up work and go home; but as his symptoms became more urgent, he was admitted into hospital that night. When admitted he was suffering from very severe dyspnœa. The resident surgeon of the hospital applied certain remedies, leeched him, and had nitrate of silver applied to the glottis, which he examined at the time. Passing his finger back he found the epiglottis quite erect, and the parts around it were tumid. The diagnosis was that the man was suffering from œdema of the glottis, for sometimes he seemed to be relieved of his symptoms; but later on they got more urgent, and he (Dr. Thomson) was sent for at about four o'clock in the morning, but when he got to the hospital the man was dead. He had been sitting up in bed with the resident surgeon sitting beside him and talking with him, when he asked to be put round upon his side, and that having been done, he suddenly died without a struggle. An opening was immediately made into the air passages, and every effort possible was made with the view of restoring respiration, but the attempt was ineffectual. On the next day the specimen now exhibited was obtained, and it was a rare one. The erect condition of the epiglottis, which was previously noticed, was preserved, and there was a great deal of serous infiltration of the sub-mucous tissues of the glottis, and passing down towards the rima they found the chink almost obliterated. The right laryngeal ventricle was almost obliterated, and there was a slight deposit of lymph upon the membrane. After the trachea and larynx had been removed, he placed them in position, and passed some water down from the tracheal extremity, and it passed through the rima simply in drops, so that possibly scarcely any air had been passing through it for a considerable time before death. The sub-mucous infiltration was limited, as could be seen at the usual point at the chords, where there was no sub-mucous tissue; but where there was a considerable amount of sub-mucous tissue the infiltration was considerable, the whole of the parts being thickened and having a velvety feel. Below the chords the lining membrane was of the ordinary character.

Mr. B. F. M'DOWELL asked how soon, after respiration had ceased, was the operation performed?

Dr. THOMSON—Immediately afterwards. I simply report what was told to me, that the moment the man dropped off, when it was thought he was dying, the resident surgeon passed the knife into the trachea. On examining the body we found a large *ante-mortem* clot in the right ventricle of the heart; this, which had passed up into the pulmonary artery. The immediate cause of death was, I believe, the sudden driving up of this clot into the artery.

TRACHEOTOMY IN DIPHTHERIA.

Surgeon-Major QUILL read a paper on "Tracheotomy in Diphtheria," which will be found at page 23.

The PRESIDENT said that before calling for any discussion he would ask Surgeon-Major Johnston to be good enough to say a few words about the operation.

Surgeon-Major JOHNSTON said he rose with much diffidence to say anything about the case, as Dr. Quill had given the Society full details of it, and had also expressed his opinions very vigorously. He was glad, however, that Dr. Quill had had an opportunity of bringing the case under the notice of the Society, because he believed it to be a case worthy of record, especially at the present time, when the subject was still one of difficulty to all practitioners. The difficulty always beset them, whether they were to cling to their medicinal treatment to the end, or whether they were to conclude with the operation of tracheotomy. They had been very fortunate in the case under notice, the child being a strong lad, one who had inherited a good sound constitution. As Dr. Quill had mentioned, whilst they were consulting as to the propriety of the operation, they had all doubts as to its necessity removed by the severe paroxysm that came on, and Dr. Banks, with great coolness, wrapped the little fellow in a blanket and laid him upon his shoulder, and throughout the operation, which was very short, there was not an inspiration; indeed, he (Dr. Johnston) hesitated to complete it, and if it had not been for Dr. Banks and his friend Dr. Quill, who both told him to go on and finish the operation, he really thought, from the dreadful appearance

of the little boy and the suspended respiration, he would have been inclined to desist. However, it was very gratifying to see the change afterwards in the patient, and he (Dr. Johnston) quite agreed with Dr. Quill when he said that every surgeon should, in a case of diphtheria or croup, in the treatment be ready with a tube for immediate insertion. There was only one or two points of special interest in the present case, and the first was as to the size of the tube. They began with a large tube, and they found what a great advantage it was to them, for on the second day, with much difficulty, a large tracheal cast was expelled, and it would have been perfectly impossible with an ordinary tube to have saved the boy's life. It was with great difficulty the cast was expelled through the large tube. They tried afterwards to diminish the size of the tube, but they were always obliged to return to the large one. They regretted very much at the time that they destroyed the diphtheritic cast; it was such a large one that they would have liked to show it to the members of the Society, as it would have removed all doubts which might have attended the case. The point which Dr. Quill mentioned as to the paralysis which followed in the case, he (Dr. Johnston) would like to refer to. Within two or three days after the operation the patient had complete paralysis of the fauces and of the pharynx, so that every drop of fluid he tried to swallow came through the tube. He (Dr. Johnston) then tried to pass a little beef-tea into the stomach with the tube; that succeeded for two or three days probably, and then it was always rejected—thrown back by the stomach, and then they had entirely to confine the support of the patient to nutritive and stimulant enemata. That went on for some days, and of course during that time the patient became very much emaciated; but after the tube was withdrawn, and the opening nearly healed, the patient's little sister tempted him with two strawberries, and he made a desperate effort to get over the strawberries. Next day his sister tried him successfully with four strawberries, and that was the crowning point of the case. There was no other case of diphtheria in the garrison at the time. Dr. Quill had taken up a very strong position as regarded diphtheria and croup; he (Dr. Johnston) for himself, would be very sorry to see the word "croup" expunged from our medical literature. It was a domesticated name, and it was one that was now given to express a very definite idea, not only with surgeons but amongst all classes of society. The difficulty, however, was to know whether there was an identity between the two diseases. He thought the majority of people would think that croup was a local affection, and that diphtheria was more or less of a general disease.

The PRESIDENT said, that before he asked the members present to enter upon a discussion of the paper, he wished to say that just before coming to the meeting he had a note from Dr. Banks, who was present at the operation, expressing regret at being prevented from attending the meeting, as he was anxious to express the great satisfaction at being present when a fine boy was rescued from impending death by the prompt operation of Drs. Johnston and Quill. Dr. Banks had given him (the President) a very graphic account of the case, and said it was one of those cases in which a human being had been taken fairly out of the jaws of death—one of the most gratifying cases that a surgeon could ever meet with, or rather where there seemed to be not the slightest doubt that it was operative skill that saved life. Dr. Quill, in his paper, had opened up a great many points that would lead to discussion, for he had by no means confined himself to the mere operative part. The last one alluded to by Dr. Johnston was not one of the least interesting as to the identifying or distinctness of what surgeons recognised as croup and what they recognised as diphtheria. He confessed he thought Dr. Johnston had very well expressed it regarding croup as generally a much more local affection than true diphtheria. He would hardly regard the paralysis of deglutition which occurred in that case as the general paralysis which occurred in true diphtheria. If they had nothing else than that remarkable difference between the two, it was enough to show that in the one case there was morbid poison and a universal affection through the system, while the other was much more usually local.

Mr. B. F. M'DOWELL said there could be no doubt at all that, physiologically, rest for the larynx was one of the great objects of the operation. As regarded the particular form of operation to be used he did not think Dr. Quill had directed himself to that branch of the subject. There could be very little doubt, indeed, in this case—speaking of the operation as an operation when discussing the vexed question whether the operation should be performed at all or not in diphtheria or croup so-called—there could be no doubt in this case that the operation succeeded, and that the child would have died if it had not been performed. He hoped Dr. Quill, in his reply, would mention what form of operation was adopted by Dr. Johnston. He (Mr. M'Dowell) presumed it was that of laryngo-tracheotomy—that it was not the deep operation. Dr. Quill, in his paper, had spoken of the after-treatment of those cases in which the operation became a necessity, and he had adverted to the late Mr. Porter's remarks on that subject. Mr. Porter stated, as well as he (Mr. M'Dowell) could recollect his writings, that all his cases died from bronchitis or pneumonia—that was, that the great majority and large percentage of his cases died either from bronchitis or pneumonia; and Dr. Quill spoke of those complications—bronchitis or pneumonia—as a result which would follow from not warming the atmosphere. He did not think that Dr. Quill had said anything about vapourising the apartment.

Dr. QUILL—Yes, I did.

Mr. M'DOWELL thought Dr. Quill had only spoken of warming the atmosphere; but there was much more importance he (the speaker) should think in steaming the air than in warming it. In several cases in which he had performed the operation he had considered it of very great importance that that should be attended to—that the air should not only be raised to a certain temperature—say, 70° or 73°—but that it should also be charged with moisture. As regards the tube, he thought Dr. Quill had said he used the double tube of Obré. He (Mr. M'Dowell) preferred Fuller's bi-valve tube, which could be got much easier into the trachea, and the inner tube was much more easily removed. Dr. Quill's paper was a very admirable and a most important one. He (Mr. M'Dowell) would not, at this late hour, enter into the question of the advisability of the operation in diphtheria or croup, but there was no doubt that the paper was an eloquent example of the advantage of the operation of tracheotomy in certain forms of disease.

Mr. W. I. WHEELER said he also had listened with very great pleasure and interest to the paper, and without going into the question of whether there was a difference between croup and diphtheria (he might say in passing that he believed there was a very considerable difference) he might mention that some time ago he also listened with interest to a paper by Dr. Thomson on tracheotomy in croup, and from what he knew of tracheotomy in croup, from his experience, he was entirely opposed to the operation, so much so, that he spoke against it in this Society. Although he had not advocated the operation, however, he had had to perform tracheotomy in croup, and the case was a successful one. He did not perform laryno-tracheotomy, nor would he do so in croup. He thought it was better to perform the operation lower down—what he might call the low operation. He would not perform laryngo-tracheotomy in croup because he thought it would not be advantageous. It was a very difficult question to decide when it was that medical remedies had ceased to act—when it was that they were called upon to have recourse to operative interference, and it was a question upon which he would be very glad to hear the opinions of others on the subject, for his mind was not made up as to when tracheotomy should be performed, and when they should say that medical remedies had ceased to act. Another question appeared to him to be of great importance, and that was, how long the surgeon should wait—to give a reasonable time—until he could perform tracheotomy with, what to his (Mr. Wheeler's) mind, could be called comparative usefulness to the patient. He thought in those cases in which they had a false membrane, so to speak, thrown down, the earlier they operated the better; but where they had got the false membrane and the broncho-pneumonia together, he thought there was but little chance of the patient's recovery. In reference to those cases recorded by Trousseau—and he had recorded a great many cases—the question had occurred to him (Mr. Wheeler), might it not be something of climatic influences which had caused the success in Trousseau's cases, which they had not got in this country?

Dr. THOMSON said a session or two ago he had the honour of bringing before the Society the subject of tracheotomy in croup, basing his paper upon some little experience he had had of the subject, and upon the observations which he had been able to make upon the cases of some of his colleagues. So far as he himself was concerned he had not been so fortu-

nate as Dr. Quill in being able to boast of a success, for in the three cases in which he had operated, although he had been able to afford considerable relief, extending over several days, to the patients, this had been uniformly followed by death. Nevertheless, he had not been in the least changed in his opinion as to the reasonableness and the propriety of this operation, and he entirely went with Dr. Quill when he so strongly urged upon all surgeons that it was not alone an unsurgical proceeding to refuse to operate under such circumstances, but that it was illogical also. It seemed to him that whether they had to deal with a disease which was local or with a disease which was constitutional, whether they held the opinion that croup and diphtheria were distinct diseases or were the same, the prominent point that came before the surgeon when he was called in to a case such as that which had been described was, whether he was to relieve that which was the prominent and urgent symptom—dyspnœa. On a former occasion he (Dr. Thomson) described what he still held—that of course in all those cases they were bound to use every medical means they could to overcome the disease; but in a large proportion of cases there came a time at which they found all their medical remedies to be unavailing, and when they had the patient simply dying by slow degrees before them. And it was in such cases as those that he thought the surgeon was bound to make the last effort in his power to admit air into the lungs. The question had been raised by Mr. M'Dowell, and he thought also by Mr. Wheeler. as to the proper moment for the operation. He (Dr. Thomson) thought it was very difficult to lay down any absolute rule as to the proper moment for the operation, and that each case would have to be judged by itself. But he thought that those who had written most on the subject, and who were accepted as the best authorities, held that when, as Dr. Quill had stated, the surgeon saw that the thorax was failing to expand naturally when the substernal and infra-clavicular regions were indrawn, when there was dilatation of the nostrils with livid countenance, and great rapidity of respiration, then, at all events, he should entertain the question whether he might not relieve by tracheotomy. The operation itself was, to his (Dr. Thomson's) mind, one of the most difficult and one of the most serious that a surgeon could have to perform; the whole surroundings of it were so alarming, the suddenness with which the symptoms came on, and the rapidity with which the operation had to be done, all those were disturbing elements, and very often they found that even the most expert surgeons came rather clumsily out of the matter. He had read of one or two cases—one case particularly came to his mind just then—a case reported as having occurred in one of the London hospitals, where the incisions were supposed to have been made in the usual way. However, the patient died; and it was subsequently found that several incisions had been made in the vertebra, but that the trachea had not been opened at all. There was one other point that Dr. Quill laid particular stress upon, and that was one in which he entirely agreed with him, for, from what he had seen of these cases, it was most desirable to use a large tube, as large a one as they could get in. In some of the cases he (Dr. Thomson) had had, the one great difficulty of after treatment had been the blocking up of the tube with hardened pellets, bringing on most violent paroxysms of dyspnœa. Another very important point that occurred in these particular cases was the question of the tracheal and bronchial membrane extending far below the wound. As Dr. Quill had mentioned, the existence of the membrane so low down was held by many writers to set any operative interference out of the question. There could be no doubt that in this instance the tracheal and bronchial membranes did exist, and the best answer that could be given to such an objection was, that the operation succeeded in the case before the Society. It was now so late in the evening that he would not detain the Society with any further observations, with one exception, and that was in reply to Mr. Wheeler's point as to the low or high operation. He (Dr. Thomson) must say that he was entirely in favour of the higher operation, not the laryngo-tracheal, but the operation above the thyroid isthmus. Any one who had done it frequently, or seen it done, would recognise the great difficulty that existed in performing the lower operation. The whole of such cases were surrounded with sufficient difficulties not to induce surgeons to make them more difficult. He would conclude by reading an extract from a letter which he had had from Prof. Spence, who, the members of the Society would remember, had written a good deal upon the subject, and who had himself operated on some 120 or 130 cases. Prof. Spence said: "I assure you it is no small honour and comfort to feel that my practice has assisted in promoting what I believe to be a life-saving operation in many cases, and in alleviating one in all. But I feel I ought to be thankful for the circumstances which led me first to operate, for I was then much prejudiced against the practice. I have recently operated successfully in a case of diphtheritic croup, so that my average is fully 1 in 3. But I think it would be a pity if averages were too much dwelt on in an operation such as this. I believe that the success will be in proportion to early operation so soon as it is evident that the chest is not expanding naturally. I have no love for the operation, I would rather do any other in surgery, but a sense of duty forces me to give the chance for life." That was the expression of the opinion of a most distinguished surgeon—the Professor of Surgery in Edinburgh, and he (Dr. Thomson) might say that it was one that all who had seen such cases would entirely concur in. He was glad to think that the importance of the question of tracheotomy was forcing itself upon surgical opinion in Ireland, and that the older objections which were urged against it in this country were dying away before the force of facts.

Dr. O'Leary said it was very important to consider the question under two heads: First, the nature of the operation, and secondly the nature of the disease. As regarded the nature of the operation, that came perhaps rather under the head of expediency and advantage in an individual case, than that they could apply a rule, and say particularly in which case it would be more applicable. But the far more important question was the constitutional or local origin of the disease. In many cases there were marked constitutional symptoms, characterised by much evidence of blood poisoning, and followed by a local manifestation in the throat and trachea, and further accompanied by well marked albuminuria, and tendency to general fibrinous deposits. The question of relying upon almost purely local treatment became then one for serious consideration. At all events, he would look more towards a discussion upon the etiology and pathology of the disease and its cause, than to any treatment, whether local or constitutional. He therefore suggested the adjournment of the debate to another night, so that a question of such importance might be dealt with as it ought to be.

After some conversation it was decided to proceed with the debate.

Dr. Henry Kennedy said he would confine his remarks to two points. In such cases of croup as required the use of tartar emetic, he had been in the habit of adding opium in one or other form to it, and he believed with very good effect. There could be no doubt that spasm played a very important part in these cases, and hence some explanation of the value of this treatment; and even the vapour round the child, could be made much more efficacious by the addition of some of the vegetable narcotics. The second point was one to which the author had called the attention of the Society in his well-given paper, viz., "As to the Identity or not of Diphtheria and Croup." On this question, he (Dr. Kennedy) held that the two affections were essentially distinct. The one was a sthenic, and the other an asthenic disease, and the treatment suited for one would be most injurious for the other. Cheyne, who had also his father's large experience to add to his own, expressly stated that in the disease he described—that was croup—the internal fauces were always healthy; and in the specimens placed in the museum of this College, it could be seen that very nearly all were similar. He (Dr. Kennedy) had had his share of fatal cases of diphtheria, but he had not yet seen a case where the child died with the symptoms of croup. He did not deny that such had occurred, though he thought it must be exceptional. Nor had he seen any case of diphtheria confined to the larynx alone, as occurred in croup But he had seen diphtheria attack the eyelids, nostrils, lips and vulva, showing the marked constitutional nature of the malady, and so bearing out what was advanced by Dr. O'Leary.

Mr. H. G. Croly wished to say that he had never listened to a paper, since he became a member of the Society, with more interest than that of Surgeon-Major Quill; and the manner in which the case had been treated, was enough to stir up all who had hitherto been opposed to the operation of tracheotomy in these cases, to at least a reconsideration of their views. With regard to the vexed question of diphtheria and croup, he thought that if they put the two words together they would go very well. They knew there were cases of what was called diphtheritic croup, and they knew there were

ordinary cases of croup. One of the most able papers on this subject was a paper by Mr. Whittle, of Liverpool, who was an advocate of tracheotomy, and who had laid down very forcibly the cases in which he operated successfully. When there was premonitary hoarseness in croup, he had always found false membranes; and when there was no premonitary hoarseness, intense tracheitis. The cases of false membrane, as a rule, were not successful. Trousseau had operated in the very early stages of croup, and had good results, which he attributed mostly to the early character of the operation. He (Mr. Croly) maintained that croup in its early stages was a manageable disease; but if they met it a few hours ahead, it was very unmanageable. He had had a case under his own care (and he presented the specimen to the museum), in which a child got a violent paroxysm of coughing, in which it coughed up a false membrane, which was a perfect cast of the larynx and trachea, and the two bronchi. False membrane, however, reformed, and the child died. The coughing up of the false membrane cured the child, but its return killed it. He had heard that if they opened the trachea they would not have a new false membrane, but that if they did not open it they would have a new false membrane. With regard to the high or low operation, he entirely concurred with the opinion that the high operation was the one in all cases where the operation was thought necessary; but he thought the question whether they performed tracheotomy, high or low, was one that must be left entirely to the discretion of the operator; but in the case before the Society it was not only the skilful, but the rapid, performance of the operation that caused the result to be of so gratifying a character. If they took it all round, tracheotomy was one of the most fatal operations in surgery; but that was no reason why they should be deterred from performing it. With regard to the tube, the larger it was the more successful the case was likely to be. He thought the teaching in Dublin had been rather to avoid tracheotomy in croup and diphtheria. It was a question of such importance that he thought none of more importance could be brought before the Society.

Dr. DOYLE mentioned a case in which he was sent for in the country to see a child suffering from carbonic acid poisoning, the effects of croup. On looking into the pharynx he could see a false membrane coming up and down through the opening of the larynx. Having failed to get a quill, he immediately cut down on the trachea by the light of a candle, cut two or three of its rings, introduced his forceps, and withdrew the false membrane, and then all the symptoms of poisoning went off. He endeavoured to get a piece of tube of some sort, but he failed, and had to leave the child, which was much better that night, and passed a good night; but on his visit next day symptoms of the membrane reforming occurred, and the child died that night. As regarded diphtheria and croup, he might mention that in the year 1875 he was attending a family of five children with measles, and in the convalescent stage secondary croup developed in the youngest, which was about three years of age. It had well marked croup, which it recovered from. He gave it an emetic, which he was very fond of giving in the first stage, tartar emetic and sulphate of copper. It was not at all a bad combination, and acted immediately. He gave generally about 20 gr. sulphate of copper with two grains of tartar emetic to two ounces of water, a teaspoonful every five minutes until vomiting was produced. The other four children, strange to say, all got diphtheria, and three of them died. None of those children had any symptom of croup. There was another symptom that he looked upon as premonitory of croup, when they had the bronchial cough, and on looking into the pharynx they saw a sort of spasm of the muscles, between which lie the tonsils.

Dr. COLLINS thought that Dr. O'Leary had opened up a very important point, as to what were the cases of diphtheria in which this operation was likely to be successful? It appeared to him (Dr. Collins) that in a case where a person was dying from blood poisoning, the operation would be of little avail; but on the other hand, when a child was dying of manifest asphyxia—not from blood poisoning—in such a typical case as that described by Dr. Quill, the operation was likely to be successful. With reference to the occurrence of bronchitic diphtheria, that no doubt was a formidable obstacle to the success of the operation; but it had been found in several cases that the want of success was not attributable to that cause. A very remarkable case of that kind had been recorded by Dr. Richardson, of London, where a child was apparently dying from bronchitic diphtheria, and large quantities of false membrane were constantly expelled through the tube, and the greatest attention had to be paid to the clearing of the tube, so much so that a skilled assistant had to stay with the child three or four nights, owing to the constant blocking up of the tube by false membrane. Notwithstanding all these obstacles to the success of the operation, the child recovered.

Mr. ORMSBY referred to the fact that Dr. Quill had stated that the late Mr. Porter disapproved of the operation strongly. Those who knew the late Mr. Porter well were aware of the fact that he merely disapproved of the operation because he had such poor success in the performance of it; and he (Mr. Ormsby) believed that had Mr. Porter been spared long enough he might have changed his opinion, and those who went by his teaching would not disapprove of the operation so strongly. He (Mr. Ormsby) could corroborate what Dr. Thomson had said regarding Mr. Spence, who the last time he was in Dublin had told him (Mr. Ormsby) that as long as he lived he would recommend the operatian.

Surgeon-Major QUILL, in reply, said that the operation performed by Dr. Johnston was the low one, through the trachea. They found it very useful in their case, and no bad result followed. They took every precaution as regarded the warming and moistening of the atmosphere. They had a blanket formed into a canopy over the bed, and that was kept in a constant state of steam by means of Dr. Wyatt's apparatus, the spout of the tube being introduced under the blanket, and was kept going day and night, the air of the room being also kept in a state of vapour. Oubré's tube was the one used. He (Dr. Quill) did not say it was the best, but it was the only one they had, and there was no time to get another, and probably if they had, the result of the case would not have been so successful as it fortunately was. He would not attempt to enter into the question of the difference between croup and diphtheria; he would only say that he did not believe there was a difference. He thought the two diseases, false croup and true croup, were a great deal mixed up, and whenever a false membrane was formed he was firmly convinced the case was one of diphtheria. Notwithstanding what Dr. Johnston had said, he (Dr. Quill) would like to banish the word croup altogether, because croup was not, in his opinion, a disease itself, but the symptom of a disease. With regard to the local and constitutional origin of the disease, he was convinced that if local treatment was employed at first, it would grapple with the disease: but he laid greater stress on the statement as to the local application preventing the spread of the disease. As regarded the operation preventing formation of the false membrane, he might add in conclusion that Mr. Bryant, of London, was also of that opinion. He was convinced that the performance of the operation in many instances prevented the formation of the false membrane after the operation was performed.

The Society then adjourned.

DUBLIN OBSTETRICAL SOCIETY.

THE second meeting of the session took place on Saturday, December 8, 1877.

Dr. DARBY, President, in the chair.

FIBROUS POLYPUS OF THE UTERUS.

Dr. M'CLINTOCK exhibited a fibrous polypus of the uterus. The lady from whom it was removed—a patient of Dr. Torney's—was about 45 years of age, and had given birth to three or four children. The only interest attaching to the specimen was the fact that the lady had been the subject of a similar complaint some years before, and about four years ago Dr. Torney and he also removed from her a polypus of the same nature as this, and about the same size. On each occasion the polypus was well marked, and had a well-defined pedicle; and it passed into, and nearly completely occupied, the os uteri, so that there was no difficulty whatever in the operation. It was the first case in his experience, which was pretty extensive, where he had had to remove a polypus that had passed into the vagina on two occasions, and each occasion the polypus being of a fibrous character. He knew it had been remarked by others that the recurrence of polypus in the same patient was extremely rare. Now that recurrence of polypus in the same patient should be rare, was rather contrary to what they would *à priori* expect—that was the recurrence of fibrous polypus; for they knew that nothing was more common than that fibrous and fibroid should

occur in multiple form, and several times in the same patient. Dr. Kidd had shown specimens to the Society which he had removed from the interior of uterus of the same patient. He (Dr. M'Clintock) had forgotten how many——

Dr. KIDD: I removed 29 from the interior of the uterus of the same patient.

Dr. MACAN asked how soon after the removal of the first polypus did symptoms of the second present themselves?

The PRESIDENT mentioned that he had removed two polypi from the lip of the uterus, but he discovered that there was a second one there at the time he removed the first. After removing the first, he had a difficulty in catching hold of the second, which was about the size of a pea, and he was obliged to wait for a few months until the second grew a little larger.

Dr. M'CLINTOCK said the interval between the two operations was nearly four years, and there were no symptoms of the second polypus for a considerable time after the first operation. The patient remained pretty well, and then hæmorrhage gradually set in, and rendered her extremely emaciated by the time it was necessary to perform the operation.

Mr. SWANZY (by permission of the Council) made a communication to the Society on

THE INFLUENCE OF THE UTERUS IN EYE DISEASE.

He said the subject was by no means a completely developed one. It was a very wide one, and its investigation was surrounded by many difficulties—not the least among them was the circumstance that very few ophthalmologists were at the same time experienced in gynæcology, and it was also rare to find a gynæcologist who knew much about ophthalmology. Much of the subject remained hypothetical; but if the interest of gynæcologists could be enlisted, more rapid and more certain progress might be made. The first disease which Mr. Swanzy referred to as probably dependent upon the uterus for its cause was iritis, occurring in otherwise healthy girls of from 11 to 17 years of age—that is to say, from about two or three years before they commence to menstruate to two or three years after menstruation has been established. Mr. Swanzy said he was unable to point to any distinct uterine disorder in these cases. The most he had been able to lay hold of was a somewhat sparse menstrual flow in those instances where puberty had been reached. Still he was strongly inclined to refer these cases to the uterus, for the following reasons:—1. Iritis was extremely rare at such an early time of life, except as the result of congenital syphilis, or as secondary corneitis. 2. He had not yet seen a case of the kind in the male; and, therefore, 3. When such cases were observed, with a certain frequency, to occur at a time of life when the uterus was approaching maturity, or had lately reached it, it was not an unfair conclusion to draw, that the uterus in some way gave rise to the iritis. This was a class of cases in which Mr. Swanzy was much interested, as he believed attention had not before been directed to a connection between the uterus and inflammation of the iris. Mr. Swanzy then mentioned neuro-retinitis, apoplexia of the optic nerve and retina, atrophy of the optic nerve, and an affection called kepiopia hysteria, as dependent upon uterine disorder, and brought forward examples from his own experience and that of others to prove the connection. He had no doubt but that the connection between eye disease and uterine disorder would be found to be even more extensive, but it was important to avoid the error of regarding every eye affection which might be concomitant with uterine disease as attributable to the latter.

Dr. KIDD thought the paper one of extreme importance. It illustrated, to his mind, the importance of medical men not confining themselves to special subjects altogether, but, while devoting their main attention to special subjects, keeping themselves *au courant* with medical science and literature. He was sorry to say that he had not followed out what he recommended, because he knew nothing of ophthalmic surgery. It had often occurred with him that he had to send a patient to an ophthalmic surgeon, with a condition of the eye which depended on uterine disease. He (Dr. Kidd) had invariably found that the diagnosis was correct, and he had invariably found that, as the uterine disease improved, the affection of the eye disappeared. It was right he should bear testimony to the accuracy of ophthalmologists, and he regretted very much that he had n light to throw upon the subject generally. One condition he had specially noticed where vision was impaired, and that was where they had uterine hæmorrhage going on. That day he had seen a lady who had a large fibrous tumour, and who suffered very much for many years from hæmorrhage. She had nearly lost the sight of her right eye; and Dr. Jacob, whom she consulted with regard to her vision, informed him that the vitreous humour was quite opaque in the right eye. He (Dr. Kidd) believed he had in many instances seen the same circumstance, where they had hæmorrhages going on a considerable time, that the eye suffered. They all knew what apprehensions women had during the puerperal state as to the preservation of their sight, and how careful they were to avoid reading or using the eyes during that condition. He believed they were quite correct in that, and that the eye was often seriously injured by reading too soon after a confinement.

Dr. M'CLINTOCK said that, although he had no experience of his own bearing directly on the subject before them, either in support or refutation of what had been advanced that night, he, nevertheless, very willingly bore his testimony to the excellence of the paper, and the care which it bestowed; and, in common with the other members, he felt very much indebted to Mr. Swanzy for having brought such a novel and interesting paper under their notice. He looked upon it that Mr. Swanzy's paper was, perhaps, more suggestive than as establishing anything decided on the subject to which it related. He (Dr. M'Clintock) thought it would require a good deal more exceptional observation to prove and to demonstrate that those diseases of the eye were really and undoubtedly the result and consequence of uterine disease. There might be such instances, and in every instance they could explain them very readily in this way—that they knew that uterine diseases established seats of inflammation in the mucous membrane, leucorrhœa, and ulceration. When women did not menstruate, they degenerated generally in health, and that produced a sort of cachexia; and such a general state of the constitution might go to any particular organ, such as the eye. He did not want, in the slightest degree, to detract from the merit or originality of the paper that had been brought forward, and he was sure Mr. Swanzy would not suppose that such could be his intention.

Dr. MACAN mentioned that Dr. Churchill gave cases in which the loss of sight was unaccompanied by any absolute disease, and where it was entirely put down to the mere occurrence of pregnancy, and which disappeared after the woman was delivered. He believed that only one case was recorded by Dr. Churchill in which a loss of vision remained after delivery.

Dr. M'SWINEY said a practical result of great interest might follow from the reading of the paper, and that was that the treatment of eye affections, which subsequently was to be traced to conditions of the uterus, would be different from what the treatment of those affections would be if they arose idiopathically, as it might be called. Obviously, the treatment was totally different from the treatment that acute affections of the visional organs would require at the hands of the physician or surgeon. Hospital physicians had recognised long since that there was such a relation existing, and other practising physicians must, he thought, have met with cases in which he was clearly aware that the affection of the eye complained of by young females—who, for the most part, were what were called hysterical females—were clearly referable to some disturbance of the uterus; and the treatment indicated quite clearly that such connection was recognised, but it was customary with physicians under those circumstances to refer their patients suffering from eye affections seriously to the care of the ophthalmic surgeon.

The PRESIDENT said that Mr. Swanzy's paper was most valuable, for it pointed out that uterine disease created or iniatiated organic disease of the eye.

Mr. SWANZY, in reply, said he only wished his paper to be regarded as suggestive. The subject was a very large and difficult one, and he hardly thought that the experience of any single observer would be enough to ascertain all that was to be found out. As Dr. M'Clintock had said, a very much more extensive field of observation would be necessary than what he had had to bring the matter to a certainty. As he said, also, it was quite possible that there were a great many cases of eye disease which might be referred to deteriorated general health, produced by the

state of the uterus, so that the eye would only be affected in a secondary way by the uterus. That was a thing which would suggest itself, and was very likely to occur. With regard to Dr. Kidd's observation, he had mentioned a case that had come under his observation of chronic uterine hæmorrhage, where one eye was affected, and where the ophthalmic appearances were those of opacities of the vitreous humour. Possibly this may have been a case of hæmophilia, or allied to that disease, and that the opacities in the vitreous humour depended on a hæmorrhage into it. Dr. Kidd had also referred to the eyes becoming affected in the puerperal state, and some others had spoken of pregnancy as giving rise to defects of sight. Those defects of sight usually depended upon one of two things—either upon albuminuric retinitis, or upon accommodative asthenopia consequent upon hypernutrophia. These affections of vision occurring in pregnancy did not come within the scope of his present paper, and therefore he had not touched upon them.

Dr. ATTHILL then read a paper on

THE INJECTION OF HOT WATER INTO THE UTERUS IN CASES OF POST-PARTUM HÆMORRHAGE,

which will be found at page 26.

Dr. M'CLINTOCK asked, Was the stream of hot water conducted directly into the uterine cavity or into the vagina?

Dr. ATTHILL said that in each case the tube passed fairly into the uterus, and nearly touched the fundus.

The PRESIDENT quite agreed with Dr. Atthill that cold water injections were not reliable.

Dr. KIDD said the Society was extremely fortunate in having brought under its notice that evening two exceedingly suggestive and important papers. The suggestion of injecting hot water into the uterus came before him as something new. He presumed, from the silence of other members when called upon to take part in the discussion, that they were very much in the same position. Theoretically, he could quite see that in many cases the suggestion was likely to be useful. He could quite understand that, in the case of an exhausted woman, hot applications would in all likelihood be useful, as water, heated to 110°, thrown into the uterus, was a powerful stimulus. It was a very important agent, for the very reason that Dr. Atthill had given—that it could always be at hand. It was the practice at the Coombe Hospital, when a patient was very exhausted, to apply over the sacrum hot napkins alternately with cold ones, to make the greater impression on the nervous sensibility. The use of hot water, in the way described by Dr. Atthill, was a very important question for the consideration of members of the Society; and he had no doubt that, when Dr. Atthill had further cases in which he brought his plan into requisition, he would give the Society the benefit of learning the results he had obtained.

Dr. M'CLINTOCK said his experience in this matter only went as far as Dr. Kidd's. They all knew and admitted that cold water was a most powerful means of checking hæmorrhage; yet, like every other remedy, it had its limits of utility, and when it was indiscriminately used, and pushed too far, it had its dangers, too. He thought it was worthy of mention that Beaudilloc, who was a most acute and accurate observer in the treatment of post-partum hæmorrhage, plainly stated that the first means he adopted for its suppression was the external application of warmth, and he said that cold, either in an aqueous or spirituous form, might be applied over the sacrum. He also recommended the application of warmth over the sacrum and over the pubis. He (Dr. M'Clintock) confessed that he would not have recourse to warm water in the first instance; he would use cold first, and then the warmth would come in afterwards.

Dr. ATTHILL, in reply, said the subject was as new to him as it was to the other members of the Society. He would remind those present that he commenced his paper by saying that cold was a most efficient remedy in cases of sudden losses of blood after delivery, where the vital powers were vigorous, and in such cases he would not think of using hot water. He merely brought it forward as an additional remedy, and would class hot water, as far as his experience went, as suitable to those cases in which he would use perchloride of iron. If, however, hot water proved, on further experience, to be an efficient remedy, he would certainly prefer it, for many reasons, to the perchloride of iron, if it were only for the sake of the comfort it gives the patient, and the extreme facility with which it can be used. Cold acted admirably where it was wished to give a shock, but where the patient cannot bear the shock, it should not be used. It seems to me that hot water will be particularly useful in those cases where hæmorrhage comes on some time after delivery, or where it has continued, though only slightly, for a considerable time. Under either circumstances the patient is usually much exhausted, and therefore the warm water is exceedingly suitable, as being a powerful stimulant. If, however, it were used indiscriminately, it would be very dangerous. To inject hot water into the vagina would be useless.

The Society then adjourned.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
AND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER VII.—TREATMENT: CURATIVE, PRESERVATIVE, AND PREVENTIVE.

FROM our statistics it will be seen that almost every known remedy has been tried, and a re-enumeration of all the medicinal agents and all the methods of treatment resorted to, from the days of Celsus, up to the present time is thus rendered almost unnecessary. As Fleming so well tells us, in the early and middle ages, magic, invocations, exorcisms, appeals to supernatural powers, and charlatanism of the grossest character, had to give way to the fatality of the disease.

Bleeding in every degree, mercury, opium, and other cerebral stimulants, chloroform, tobacco, the acids and alkalies, oil of turpentine, cantharides, tar, white hellebore, ceradilla, the salts of lead and those of iron, nitrous oxide, inhalations, the injections of warm water and narcotics into the veins, electricity and galvanism, the hot vapour and hot air baths, even the poison of the viper, have all been tried, and with the same sad results.

Cases of recovery have been recorded, as may be seen from our tables, but the same treatment when employed in other cases has unfortunately failed.

But these instances of recovery, however, as we said in our introductory chapter, should inspire us with confidence in the resources of medicine, and should lead to a rational mode of treatment, especially as we have proved that we have a clearer and more rational comprehension of its pathology. We cannot, then, abandon to their fate those who exhibit indications of the disease, and in the face of our evidence we need not any longer perpetuate the error, that it is infallibly mortal. The time has not long gone by, since, because of the supposed inevitable death of the patient, and the horrible sufferings undergone before dissolution, human beings were destroyed by suffocation, instances of which we shall give in our chapter on the curiosities of the medical literature of this disease. But we are emerging into a clearer light, and we have at the present time some confirmation for our opinion, that the remedy for this disease may probably be at hand. In our issue of June 13th, 1877, we said in the face of so incurable a malady, which has taxed all the resources of the materia medica, and which carries off so quickly and so terribly the unfortunate subjects who are bitten, it was pleasant to record a case of recovery, which we gave, as reported by the *All. Med. Berl. Cent. Zietung.*

We also said, enthusiasm about new remedies was not wise, as but lately another alleged specific, the Xanthium spinosum, recorded in the same number, had not maintained its reputation. (*a*)

(*a*) We had reason to complain that our account of the Xanthium spinosum had been copied by other journals and papers without acknowledgement.

The remedy used was curare, and we observed that one single case did not prove anything, but that the physiological action of curare, reasonably encouraged us to make further experiments with it.

We were then aware of the history of the woorali poison, and of the antecedent efforts made not only by English medical men, but laymen, to use it as a remedy; but unfortunately this had not been done in the past, nor at the present time can we say with certainty that the woorali is a specific, though we have the gratifying assurance of three successful cases, two as reported in the *Veterinary Journal*, one in our own pages. It must be tested scientifically, and under the conditions we shall lay down, by some competent observers, and with the data we have, we may reasonably hope that by its judicious application, rabies may be shorn of its terrors.

We have shown in various portions of our report that there was a shadowing forth in the past of some of the truths, in regard to rabies, and that some of the older physiologists had undefined, though as it has been proved, accurate ideas of its pathology. If the curare should maintain its position, it will again illustrate that we have been forestalled. To a member of the veterinary profession we are indebted for the merit of recommending curare in cases of rabies.

Professor Sewell was the first who suggested the idea, and Waterton who went in quest of the poison, and acquired it in its pure state at his own expense, and at the cost of his own health, has generously given him the credit of the discovery. Sewell, on the authority of Waterton, is said to have declared before Sir Joseph Banks, and a large company of scientific gentlemen, that, were he unfortunate enough to be bitten by a mad dog, and become infected with rabies, he would not hesitate one moment in having the woorali poison applied, as he felt confident that the application of it would prove successful.

The history of this poison is most interesting, and we must linger for a short space on it.

Taylor, in his classic work on "Poisons," quotes Waterton's account, and this offers us some guarantee of the veracity of the much-abused naturalist. We shall give an abridged account from the original work, from the folio edition, 1825.

In the month of April, 1812, Waterton left the town of Stabrock to travel through the wilds of Demerara and Essequibo, with the chief object of collecting a quantity of the strongest woorali poison, and after penetrating into the country where the poisonous ingredients grew, where the composition was prepared and used, success attended his adventure. After 121 days he acquired all the information about it, and a supply, which he brought back with him to England. The poisonous extract is made from the woorali vine, a bitter root, two kinds of bulbous plants, two species of ants, the strongest Indian pepper, and the powdered fangs of the labarri, and counacouchi snake. The Macoushi Indian makes the best preparation. Having found the necessary ingredients, the Indian scrapes the woorali vine and the bitter root into thin shavings, and puts them into a kind of colander, made of leaves; this he holds over an earthen pot and pours water on the shavings; the liquor which comes through has the appearance of coffee.

When a sufficient quantity has been procured, the shavings are thrown aside. He then bruises the bulbous stalks, and squeezes a proportionate quantity of their juice through his hands into the pot. Lastly, the snakes' fangs, ants, and pepper are bruised and thrown into it. It is then placed on a slow fire, and as it boils, more of the juice of the woorali is added, according as it may be found necessary, and the scum is taken off with a leaf. It remains on the fire till reduced to a thick syrup of a deep brown colour. As soon as it has arrived at this state, a few arrows are poisoned with it to try its strength. If it answers the expectations it is poured into a calabash, or little pot of Indian manufacture, which is carefully covered with a couple of leaves, and over them a piece of deer skin, tied round with a cord. They keep it in the most dry part of the hut, and from time to time suspend it over the fire to counteract the effect of dampness. The operation of making it was gloomy and mysterious. No women or young girls were allowed to be present, lest the Zabahout, or evil spirit, should do them harm.

The shed under which it had been boiled was pronounced polluted, the pot must never have held anything before, whilst the maker had to fast as long as the operation lasted. We may now consider that all the ingredients mentioned are not necessary to produce the effects of the poison, but that they were added through the superstitious feelings and custom of the natives. According to Waterton and Taylor—

1. The extract is so miscible with water that the slightest moisture dissolves it, hence it speedily diffuses itself when introduced into a wound.

2. The symptoms are stupor and paralysis; it does not produce any apparent effect, until after the lapse of one or two minutes, and the wounded animal apparently dies without a struggle, and without pain.

3. The flesh of the animal thus killed may be used as food.

4. The dose must be proportioned to the size of the animal.

5. Like the serpent-poison, it is active when introduced into a wound, but almost inert when taken into the stomach (Bernard).

6. Animals poisoned by it have been restored by keeping up artificial respiration, as instanced by the ass "Wouralia," and by the experiments at Nottingham, in which Dr. Sibson took part.

7. The extract retains its power for an indefinite period, but unless kept dry it is liable to become weakened in its properties.

8. The effect is to destroy the motor power of the nervous system, and the observations of Kolliker and Pelikan show that its action is the very opposite to that of strychnia. M. Bernard remarks that there is no direct relation between the chemical character of a substance and its physiological effects. The same, or similar, chemical characters, may exist in two bodies—curarina and strychnia—of which the physiological effects are not only different but antagonistic.

9. We may mention, as a memorandum to be borne in mind, that, according to Taylor, curara, which has but a slight action when swallowed, would, however, give the chemical reactions of strychnia, in the stomach, and thus induce some chemists to swear, that beyond all doubt strychnia was present, and that the person must have died from it.

In taking leave of Waterton and his woorali, we must direct attention to the following remarks made by him in 1844:—

"It is an acknowledged fact that the art of medicine has hitherto been unable to arrest the fatal progress of confirmed hydrophobia. This being the case, it is both wise and expedient to give the sufferer a chance of saving his life by the supposed, although as yet untried, efficacy of the woorali poison; which, worst come to the worst, would by its sedative and narcotic qualities, render death calm and composed, and free from pain; a circumstance not to be expected under the ordinary treatment, or no treatment at all, of this ungovernable and fatal malady."

It is thus with every suggestion and invention; like many diseases, they require an incubative period, before they take shape and form.

The woorali of the present day, is differently prepared from that of the Indian preparation. It is called curara, and has many synonyms: *Ourari*, *Urari*, *Woorari*, *Woorara*, *Wourali*, *Wouraly*.

Besides the writers we have mentioned—Waterton, Taylor, Bernard—who have described this poison, the most recent authority is Schomburgk, who states that it consists alone of vegetable matter, and chiefly of an extract of the bark of *Strychnus toxifera* (N. O. *Loganiaceæ*), a tree found native in Guiana. Waterton, as mentioned,

describes his woorali poison as soft, whilst other writers speak of the necessity of keeping it in a perfectly dry state. Taylor ("On Poisons," 1875) says that "curara is a brownish-black brittle substance, having the appearance of Spanish liquorice. It dissolved slowly in cold water, but rapidly when heated, producing a turbid brown liquid; this became clear upon filtration.

We have mentioned in our chapter of "General Conclusions" the solution which is prepared by Messrs. Corbyn, Stacy, and Co., and we have since received some discs prepared by Savory and Moore, who inform us that curara is an indefinite substance, the botanical origin of which is still uncertain; it is, however, the juice of some plant solidified or dried with variable quantities of extraneous matter. The active principle in this drug is an alkaloid obtained by Boussingault, as a non-crystalline, yellow, horny mass, deliquescent, capable of turning red litmus blue, and uniting with acids to form salts. Although curarine, the alkaloid of curara, possesses some of the characteristics of strychnine, sufficient proof has been obtained (*Vella. Pharm. Journ.*, vol. ii., p. 213) that it is totally distinct from the latter, and that their action is antagonistic.

Preyer was the first to isolate curarine in the crystalline form; according to him it has the formula $C_{10}H_{15}N$. It is very hygroscopic; has a very bitter taste; crystallises in colourless four-sided prisms; dissolves freely in water and alcohol, less easily in chloroform and amyl alcohol; and is insoluble in anhydrous ether, benzol, turpentime, and carbon disulphide. It acquires a splendid and permanent blue colour in contact with sulphuric acid, purple, red with nitric acid, and violet with potassium dichromate and sulphuric acid (like that of strychnia, but more permanent). Its hydrochloride, nitrate, sulphate, and acetate are crystallisable. Dragendorff also finds that curarine is quite distinct from strychnine, and that a very active curara occurs in commerce in which neither strychnine nor brucine can be detected. His "Manual de Toxicologie" contains an excellent chapter on curarine.

(*To be continued.*)

The Medical Press and Circular

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 9, 1878.

HYDATIDS OF THE LUNG.

THERE are several diseases which seldom or never come under the observation of the European practitioner, but which are of frequent occurrence in other parts of the world. Such are true leprosy, the fungus foot of India, yellow fever, hydatids of the lung, &c. There are several English works on medicine in which the last-mentioned disease is scarcely noticed. Among modern French authorities, Andral records only five cases. Bricheteau only saw two cases during a practice of more than forty years. Monneret only saw one case, which was detected *post-mortem*. Trousseau has in his clinical lectures devoted several pages to the consideration of the disease, but allows that he has seen only two cases during life. Yet pulmonary hydatids is endemic in some countries, as in Iceland and Australia, and it is so common in Victoria, that any medical man in practice in that town has had the opportunity of seeing many scores of times more cases than any of the leading authorities in Europe. Dr. S. Dougan Bird has recently published a valuable monograph on the subject which is the result of the experience of sixteen years of practice in that colony, and from this we propose to draw attention to the more important points that have been established by the experience of Australian practitioners.

With regard to the diagnosis of hydatids of the lung, the only absolute evidence of their existence is by the appearance in the sputa of the characteristic cysts or portions of them, or fragments of the hooklets of echinococci, but this does not happen till that stage of the disease in which the entozoon has begun to die and to be expelled from the body. The general symptoms may be very slight even in cases where the cyst has attained a great size, but usually some signs of pressure or irritation, dyspnœa, and duskiness of the skin, or more or less phthisical cachexia, progressive loss of flesh, cough, mucus, and afterwards purulent and hydatid expectoration are noticed in the course of the disease. Visible venous engorgement from pressure is rare, and often forms the distinguishing characteristic of intra-thoracic cancer from hydatid. The physical diagnosis of the disease is given with more precision by our Australian authority than by any European physician. In the opinion of the latter there are no means of distinguishing solidification of the lung from unbroken hydatid cyst, the sputa alone being characteristic of the disease. But according to the large experience of Dr. Bird, the physical signs are:—Expansion more or less deficient in the affected side, mensuration but little affected, absolute dulness on percussion, with absence of respiratory sound over a space of the chest wall not smaller than the palm of the hand, generally in the lateral or intra-clavicular regions, with absence of vocal fremitus in most cases. This dull space always presents a rounded outline, is limited by a line of demarcation so exact that it can be mapped out with pen and ink, and is unaltered by position. Beyond the boundary line percussion is clear and normal. The respiratory sounds, though inaudible over the dull surface, commence immediately beyond the pen line, and though probably rather harsh and puerile in character, are indicative of healthy lung tissue. Besides this, the distinctive vibratile thrill of fluid may sometimes, but not always, be detected by percussion over the intercostal spaces. A localised pleuritic effusion, confined by adhesions, would fulfil the above physical signs; but such a state of things is very rare, and would probably be preceded by a history of pain and febrile symptoms. In fact, one is reduced to the conclusion that there is a sac containing fluid within the chest wall, slowly enlarging, causing little or no pain or local irritation, not the result of any inflammatory effusion, but foreign to, though growing in, the thoracic viscera. A hydatid cyst alone combines all these characters, so that the diagnosis may be reduced almost to a certainty. Nevertheless, when the cyst is only of moderate size, and does not impinge on the chest wall so as to give the physical signs of fluid, the diagnosis may be impossible unless the sputa are characteristic of hydatid.

Whatever may be thought of the confidence which the

Victorian physicians have in their ability to recognise the presence of a pulmonary hydatid cyst, the prompt and heroic measures, they take for its treatment is quite in accordance with the precision of their diagnosis.

"Of the specific treatment of pulmonary acephalocysts," says Dr. Walshe, "little is known."

Dr. Fuller remarks that "treatment is of little avail in cases of intra-thoracic hydatid." Other authorities, English and Continental, entertain a similar opinion, and, therefore, it is gratifying to hear that in a country where the disease is so prevalent operative treatment is frequently and successfully practised. The tapping of the cyst by Dieulafoy's pneumatic aspirator is not in favour with the Victorian surgeons. The operation is performed with a very fine trocar, not less than six inches in length, furnished with a very sharp stylet. As soon as the diagnosis is determined on, and after a small incision in the skin has been made, the trocar is "introduced with a firm and fearless hand" till fluid is reached. Care must be taken to avoid the neighbourhood of the main vessels and bronchi, but one or two failures to reach the hydatid are not attended with any subsequent mischief. After the cyst has been emptied the only and almost uniformly successful treatment advised is to employ internal remedies, the bromide or iodide of potassium and kamela, or turpentine by the stomach or inhalation, and to tap again with the fine trocar if the cyst re-fills. No interference is recommended when the natural rupture of the cyst has taken place unless it is very large, old, and in close proximity and probably adherent to the chest wall. In the latter case the cyst is treated as an abscess, and an opening is made between the ribs to allow of the evacuation of its contents. Of this radical cure of old suppurating cysts by their entire removal through an incision between the ribs several interesting cases are recorded in the monograph to which we are now drawing special attention, and to which we must refer the reader who is desirous of more information on the subject. Altogether the extensive and very satisfactory experience of Australian practitioners with regard to the diagnosis and treatment of pulmonary hydatids has certainly added much to our previous knowledge of the subject, and has, at all events, afforded fresh evidence of the fact that the puncturing of the lung with a fine trocar, and even the extirpation of the cyst from without, are not attended with the danger that was formerly attributed to operations of this nature.

UNIVERSITY OF LONDON.—ADMISSION OF WOMEN TO DEGREES IN ALL FACULTIES.

During the ensuing week Convocation will meet to consider a supplementary charter for the University of London, which will, if granted, enable women to become candidates for the examinations in all faculties. It may be interesting to recall the actions of Convocation which have directed the Senate to frame this supplementary charter. The members of Convocation passed a resolution in favour of the admission of women to degrees in medicine, and the Senate, acting upon the resolution sent up to them, resolved by a majority of two to one to take advantage of the Russell Gurney Act, an Act which enabled any examining body to admit women to the examinations, and to grant them the registrable degree or diploma, as the case might be, *sans* all other rights which such degree or diploma conferred upon men. To this action of the Senate the medical graduates, perhaps not unreasonably, demurred, and appearing in force at the next meeting of Convocation, resolved that it was undesirable that the University should admit women to degrees in medicine before having considered the advisability of admitting them to degrees in all faculties.

The Senate have now taken into their careful consideration this second resolution sent up from Convocation, and out of it arises the supplementary charter in question.

In what way will the medical graduates vote at the forthcoming meeting?

Doubtless many who supported the resolution believed that to admit women to the practice of medicine was a step in the wrong direction, for divers reasons, and, therefore, though they were unable to prevent women studying medicine, other examining bodies having opened the way for them so to do, yet it was their duty to obstruct their advance. Others, as the framing of the resolution expresses, considered it unreasonable that women should be admitted to degrees in medicine, whilst, at the same time, excluded from faculties more suitable for them. Now, both these classes of supporters of the resolution may still conscientiously refuse to support the Senate, the former for the same reasons that have already determined their actions, and the latter for the reason that they differ from the Senate as to the advisability of admitting women to degrees at all. But by such action their object would not be attained.

Convocation have the power to negative the proposed changes in the constitution of the university, and should a resolution be carried to that effect, women desirous of graduating in arts and science can look only into a gloomy future for some enabling act to come to their aid. But for those who desire to graduate in medicine such an act is already in existence, and a resolution stands on the minutes of the Senate passed by a majority, and at a subsequent meeting confirmed by a majority of two to one, to the effect that regulations shall be made for the admission of women to degrees in medicine. We believe that a committee is still in existence for the consideration of these regulations, and that its sittings are only delayed pending the vote of Convocation on the addition to the University charter. It is, therefore, probable that the medical graduates, recognising the fact that, under any circumstances, women will shortly be admitted to degrees in medicine at the University, will not interfere with their admission to examination in other faculties.

Notes on Current Topics.

Harveian Society's Conversazione.

The annual meeting of this Society was held on Thursday evening, January 3rd. The rooms have recently been re-decorated, and present a pleasant appearance. The usual council meeting was held before the *conversazione*, and it was found that the finances of the Society were in a most healthy condition; indeed, the Society is

now in a position to afford grants for scientific work. In the absence of the ex-President, Mr. Carr Jackson, who retired during the session in consequence of impaired health, but is now recovering, the chair was taken by Mr. W. F. Teevan. By the exertions of the Secretaries, Mr. Henry Sewill and Dr. Fothergill, and a committee, the meeting was of an unusually attractive character. Telephones communicating between different rooms of the building were exhibited in action all the evening, and were surrounded by a crowd the whole of the time. A volume of photographs of "Bulgarian Atrocities" was lent by Ernest Hart, Esq., and excited much attention. Microscopic objects of great interest were exhibited by Dr. Ferrier, Dr. Mahomed, and Mr. Henry Power. Paintings and other objects of art were exhibited by Mr. Seymour Haden, Dr. Farquharson, Dr. Cheadle, Dr. Braxton Hicks, Dr. Evershed, and others. A new feature was added in the form of some first-rate instrumental music. The attendance was much larger than was ever known before, and among the visitors were the President of the Royal College of Physicians, Dr. J. C. Bucknill, Mr. Curling, Dr. Crichton Browne, Dr. Langdon Down, Dr. Lockhart Robertson, Dr. Broadbent, and other prominent members of the profession. Should the succeeding annual *conversaziones* of this flourishing Society be as successful as the present one has been it will be necessary to hold them in larger rooms than are at present at the Society's command. The following is a list of the newly-elected officers of the Society :—

President.—W. M. Graily Hewitt, M.D., F.R.C.P.

Vice-Presidents.—William B. Owen, Esq.; Hughlings Jackson, M.D.; John Easton, M.D.; E. Symes Thompson, M.D.

Treasurer.—Henry Power, Esq.

Hon. Secretaries.—Henry Sewill, Esq.; J. Milner Fothergill, M.D.

Council.—George Eastes, M.B.; Robert Farquharson, M.D.; Alfred Meadows, M.D.; Percy Boulton, M.D.; Stamford Felce, Esq.; F. J. Gant, Esq.; George Field, Esq.; T. Carr Jackson, Esq.; Walter Cheadle, M.D.; Granville Bantock, M.D.; N. H. Stevens, Esq.; Alfred Wiltshire, M.D.

Hot Water Injections in Post-Partum Hæmorrhage.

We print in another column a short *résumé* of a paper read by Dr. Atthill at the last meeting of the Obstetrical Society which is, we think, well calculated to arrest the attention of the profession. In it he gives the particulars of two cases where serious post-partum hæmorrhage was immediately and permanently arrested by the injection into the uterus of water at a temperature of about 110° Fahr. Dr. Atthill does not claim any originality for the idea, but, nevertheless, we think he deserves great credit for his courage in putting this method to the test, and for his promptness in bringing the results of his experience under the notice of the profession. This method is not intended to supersede the application of cold, but is available in cases where cold has either failed, or has been used too long, or when the system is too exhausted to respond to stimulus.

In both the cases given cold had already been tried unsuccessfully, and one case was so serious that Dr. Atthill was prepared, should the hot water also fail, to have recourse to the perchloride of iron.

Perhaps the most interesting fact mentioned is the effect that was produced on the pulse, which immediately became much stronger, the patient, at the same time, experiencing a grateful sensation of warmth. It is not, however, in cases of post-partum hæmorrhage alone that Dr. Atthill has put this method to the test. He has also used it in cases of non-puerperal uterine hæmorrhage, and stated his intention of laying the results thus obtained at no very distant period before the profession. There are many other points of interest in the paper, but we think we have said enough to show that the method is deserving of the confidence of the profession, both on account of its own merits and also on account of the high reputation deservedly enjoyed by the present energetic Master of the Rotunda, by whom the practice has been successfully inaugurated in this country.

Vital Statistics—London in 1877.

In the course of the fifty-two weeks that ended December 29th there were 127,258 births recorded in London, exceeding the deaths by 50,256. In the same period 77,002 deaths were registered, being equal to an annual rate of 21·8 per 1,000 inhabitants. The year 1877 was a remarkably healthy one, only two lower rates standing on record. The deaths include 14,805 in workhouses, hospitals, and other public institutions, an increase in the year of 880. There were 4,916 deaths inquired into before coroners, and 2,572 were due to violence, a decline of 313 ; there were 18,549 deaths below six years of age, and 2,544 at sixty and upwards. Small-pox caused 2,544 deaths in the year, the highest total reached since 1871. Measles, too, were very prevalent, 2,347 fatal cases having been recorded, against 1,741 in the previous year. Scarlet fever has fallen in the year from 2,297 to 1,576 ; diphtheria, from 359 to 317 ; and whooping-cough, from 2,739 to 1,780. Diarrhœa was remarkably below the average rate, 2,479 fatal cases only having been placed on record. Of marriages during the year, 34,072 were celebrated, most of which took place in the Established Church, 29,661 being thus returned, against 4,411 in various chapels and in the district register offices. Of the remaining 4,411 marriages, 1,098 were Roman Catholic marriages, 1,341 were of other Christian denominations, 1,650 took place in the register office, 3 were of Quakers, and 319 of Jews. There were 27,659 marriages of bachelors and spinsters, 1,637 of bachelors with widows, 3,017 of widowers and spinsters, and 1,759 of widows and widowers. There were 4,776 widows married, and 3,396 widowers. There were 1,610 marriages of men under twenty-one, and 5,712 of women.

Death of Ruhmkorff, the Electrician.

The sudden death is announced, on December 20, at Paris, of Henry Daniel Ruhmkorff, whose name is so closely connected with the history of magneto-electricity. He was born in Hanover, Germany, in 1803, and but little is known of his early life. In 1819 he wandered to Paris and obtained a position as porter in the laboratory of Prof. Chas.

Chevalier, at that time one of the leading French physicists. Here he displayed a remarkable fondness for electrical apparatus, as well as ingenuity in its arrangement, and was enabled shortly after to start a modest manufactory of physical apparatus. Through the efforts of Chevalier and the excellence of the work performed, the business was rapidly extended. In 1844 Ruhmkorff brought out his first invention, a convenient thermo-electric battery. Soon after he turned his attention to magneto-electricity, especially the production of the induced currents, discovered by Faraday in 1832. A long series of experiments resulted in the appearance, in 1851, of the famous "Ruhmkorff coil," with its later modification, the most important piece of apparatus in this branch of physics. With this powerful adjunct the electrician was enabled to obtain sparks 18 in. in length, pierce thick plates of glass, and carry out a vast variety of experiments. The invention was rewarded by a decoration and medal at the Exhibition of 1855, while in 1858 it received the first prize of 50,000f. at the French Exhibition of Electrical Apparatus. M. Jamin delivered an address over the grave, in which he stated that Ruhmkorff died almost a poor man, because he had spent all his earnings on behalf of science and in works of benevolence.

Clinical Instruction at the Belfast Workhouse Hospital.

At a meeting of the Belfast Board of Guardians held last week, and recorded in a contemporary, a discussion took place in reference to this matter. It seems that the authorities of the Queen's College were anxious that the medical students should have the advantage of the clinical instruction which the hospital and infirmary of the workhouse afforded; and at an interview some time since between them and the guardians, it was arranged that the latter should give every facility as far as they could in accordance with the proper discipline of the house. It was also agreed that Drs. Smyth and McConnell should have the same status as clinical instructors as the medical officers of the Belfast Royal Hospital. The question of remuneration, however, upset the whole arrangements; for as the fees of the students were divided equally among the medical officers of the Royal Hospital, and as they did not wish to curtail their emoluments by transferring a portion to Dr. Smyth and his colleague, it was suggested that an increase of fees should take place, so that the amount per share might remain as formerly; but the College authorities made objection to this procedure, and so the matter remained as before. The subject was now brought forward for discussion, and it was agreed by the guardians that copies of the rules adopted by the Board as to the admission of medical students to the Union Hospital for clinical instruction, should be forwarded to the Chief Secretary for Ireland, requesting him to cause an inquiry to be made why the opportunity afforded the students had not been embraced.

Lunacy in Essex.

The increase of lunacy in Essex is giving considerable trouble to the authorities. The total number of lunatics now under charge of the county magistrates is 936, being 16 more than there is proper accommodation for at the county asylum at Brentwood. The consequence is that a number have to be provided for at a temporary home at Mistley, or sent at great expense to asylums in other counties. Steps have been taken to provide a new additional asylum for 300 patients at Wickham Bishops, near Witham, but building contracts will not be entered into until a supply of water has been obtained. Boring operations have been going on for eight months, and the depth at present attained is 240 feet. The magistrates have memorialised to be relieved of the maintenance of a number of lunatic soldiers sent to the asylum, simply because they are landed on the Essex coast from India.

The Small-Pox Epidemic at Harwich.

Since our last report there have been some 16 or 17 more cases of small-pox at Harwich and 10 cases of smacksmen on the river, and others have been taken to the hospital at Ipswich, all cases of illness in harbour waters, being under the terms of a local act, subject to the Ipswich sanitary authority. Now that the isolation policy is being adopted, the popular scare has subsided. Those attacked are being attended to in the temporary hospital formed of a number of cottages thrown into connection with one another. There are already more than thirty patients in it, under the care of Dr. Jeffrey M'Carthy. A relief fund has been opened, and the mayor has called a meeting of subsribers. Up to the time of going to press, there had been twenty-one deaths chiefly of persons about eighteen years of age, scarcely any of whom had ever been vaccinated.

The Automatic Method of Reducing Luxations of the Hip.

In the "Periscope" of the *Hosp. Gazette and Archives of Clinical Surgery*, Nov. 1877, E., of Birmingham, notices the successful treatment of some cases of this accident, by the above method, the credit of which is due, in the first place, to Dr. Allen, who accidentally discovered it in 1875, whilst lifting a patient into a suitable position for attempting reduction; in the second place by Dr. Crosby, who successfully applied it in several instances, and who has the credit of having first given it to the profession, his first case being published in the *Phila. Med. Times*, June 23, 1875.

The first of Dr. Crosby's patients had typical dorsal dislocation of the hip. To reduce it, the patient was placed on his back on the floor, lying on a blanket, he was thoroughly anæsthetised, in order to obtain complete muscular relaxation. The legs were flexed at right angles to the thighs, and the latter similarly flexed upon the pelvis, for the purpose of removing the strain from the ileo femoral or Y-ligament. Dr. Crosby then placed his hands under the calves of the legs, quite near the knees, and raising the pelvis a short distance from the floor, made very slight abduction of the affected limb, when the head of the bone at once slipped into its normal position. The extending force was the patient's own weight.

Cheap Court Surgeons.

A correspondent of a contemporary tells the following story: In Aberdeen, there is an institution called a "Mutual Assurance and Friendly Society for Health,

Life Assurance, and Medical Attendance." The amount paid for "medical advice and attendance to the members subscribing, their wives, and such of their children as are under fourteen years of age," is about four shillings and eightpence *per annum* for each family. The medical attendant to this society is—to give him all his titles—a Doctor of Medicine, Doctor of Laws, and Fellow of the Royal Society, all of Edinburgh; and Honorary Member of the Clinical Society of London, a Professor of Surgery in a Scotch University, Senior Surgeon to a Hospital, and a Surgeon to the Prince of Wales for Scotland. He may also be considered a leading consulting physician and surgeon in the north.

"I am," says the writer, "a poor general practitioner, and when I send in my modest bill for medical attendance, I am often met with grumbling at the amount, and a gentle hint for a much smaller sum in the above society the eminent services of a professor and court-surgeon can be obtained."

Fucus Vesiculosis and its Use in the Treatment of Obesity.

Drs. Duchesne-Duparc and Godefroy recommend the use of an extract of the *fucus vesiculosis*, or bladder wrack, one of the most common sea-weeds found on the coasts of Europe and America, for the purpose of reducing obesity. Dr. Godefroy gives his personal experience of the effects of this drug. He took 4½ grains of extract thrice daily, at the commencement of a meal, with the effect of reducing his weight nearly three and one-half pounds within thirty-four days. M. Dannecy gives the method of preparing the extract in the *Journal de Pharmacie*, Nov. 1862, p. 434. Of this extract, 3¾ grains may, at the outset, be taken thrice daily, and the dose gradually increased to about three times that amount. A very good extract of this drug is prepared by Theodore Metcalfe, & Co., Boston, U.S., the usual strength of one grain to the minim being followed, and the dose for an adult being one-half to two teaspoonsful. Price to physicians being $2-50 each pint bottle, $8-50 per dozen 4 ounce bottles. Caution is necessary not to confound the *fucus vesiculosis* with the *f. nodosus* and the *f. serratus*. It is believed that the mistaken use of these latter, has given rise to disappointment in the treatment of obesity.

Opium in Epilepsy.

Now that bromide of potassium and other remedies are so frequently prescribed in the treatment of this disease, the practitioner is too apt to lose sight of the fact that one and the best of our old narcotics may be frequently administered with success in certain forms of epilepsy. In the Ohio *Medical Recorder* for Noevmber, Professor D. Todd Gillman has given his personal experience in the use of opium in this disease, especially in that form of it which had its origin in drunkenness, pain, traumatism, and heredity. He declares that his success has been uniform, and that in every instance he has been able to arrest the paroxysms, and in one notable instance the opium succeeded after other remedies had failed. Opium was recommended for epilepsy by some of the ancient writers and in more modern times by Fothergill and Cullen. I should, however, be cautiously prescribed, otherwise it may do more harm than good.

The Irish Registration Amendment Bill.

We are pleased to learn that the Bill for amending the registration system in Ireland, and assimilating it as far as possible to the English system, has been examined and approved by the Public Health Committee of the Dublin Town Council, who will be recommended to petition in its favour when it is introduced into parliament. The Bill was prepared by the Irish Medical Association, and we understand is strongly approved of by the registration department, and it is hoped that it may be one of the Irish measures of the Government in the coming session.

Serious Illness of King Victor Emmanuel.

The King of Italy is suffering from an attack of violent fever, associated with pleurisy in the right lung. The course of the fever gives rise to the apprehension that it may prove te be a complicated case of miasmatic fever. On Saturday night the King slept several hours, perspiring very freely, and there appeared a slight improvement in the symptoms. On Sunday, however, towards two o'clock the temperature again increased. Latest accounts say that the King's symptoms are taking a favourable turn.

At the pending inquiry by the Local Government Board into the management of the Holborn Workhouse, we learn from our contemporary, the *Weekly Dispatch*, that one of the accusations to be brought forward is that a book of blank certificates of death, duly signed by the medical officer, was left out during this gentleman's absence from town, so that the unqualified assistant might at any time fill them up with the name and age of the pauper whom his unskilled nursing may perchance have brought to an early grave.

The most recent official return gives the following rates of mortality per 1,000 of the population of the principal foreign cities: Calcutta 45, Bombay 40, Madras 101; Paris 27; Brussels, 25; Amsterdam 28, Rotterdam 26, The Hague 16; Copenhagen 21; Stockholm 25; St. Petersburgh 34; Berlin 25, Hamburg 26, Dresden 22, Munich 34; Vienna 28; Buda-Pesth 43; Rome 22, Naples 28' Turin 30, Venice 27; New York 20.

The last week's official return of the English Registrar-General, is more satisfactory than its predecessor. The mortality in Edinburgh was reduced to 22 per 1,000 of the population, Glasgow 23, London 26, and Dublin 27. The highest death-rate reached was 33 per 1,000 in Sunderland and Plymouth. Small-pox was less fatal in London, and there was but one death from this disease throughout the rest of the kingdom.

Within the London metropolitan area last week 50 deaths were reported to the Registrar-General from different forms of violence; 47 were the result of negligence or accident, including 12 from fractures and contusions, 7 from burns and scalds, 8 from drowning, and 15 of infants under one year of age from suffocation.

The degree of Bachelor in Surgery (B.Ch.) in the University of Dublin, was conferred upon John Fitzhenry Woodroffe, *stipendiis condonatis*, in consequence of his having double first place at the recent examinations for the degrees of Bachelor of Medicine, and Bachelor in Surgery.

A LAMENTABLE occurrence took place last week in the county of Limerick. A young gentleman named Vincent, connected with most of the principal families in the county, while eating his dinner was suddenly asphyxiated, and before any medical relief could be afforded, expired.

SCARLET FEVER is excessively prevalent and fatal in Sheffield; whilst whooping-cough is quite epidemic in Birmingham and Plymouth.

SEVERAL cases of small-pox have recently occurred in the wards of St. Bartholomew's Hospital. These patients have, however, been isolated, and the restrictions upon the other inmates removed.

THE ADDRESS TO DR. DARBY, OF BRAY.

WE referred last week to the presentation of addresses to Dr. Darby by the medical officers and the executive officials of the Rathdown Union in testimony to their appreciation of his services to the Union during his thirty-seven years of connection with it, which has recently terminated. We now give the addresses themselves and Dr. Darby's reply. It cannot but be very gratifying to Dr. Darby that an unswerving discharge of his duty during so long a period has gained for him the warm friendship of those who had the best opportunity of knowing his worth.

Address of the Executive Officers of the Workhouse.

DEAR SIR,—We, the undersigned, being office-bearers in the Union of Rathdown, on the occasion of your retirement from the active services you have rendered as Medical Officer of the Institution during the lengthened period of thirty-seven years, hereby desire to express our heartfelt recognition, not only of the value of the professional skill which you have brought to the alleviation of suffering, amongst many members of our families, but of the uniform kindly feeling, friendly counsel, and urbanity of manner which have ever marked your intercourse with us.

In requesting your acceptance of the accompanying token of our gratitude and esteem, we earnestly indulge the hope that you may be long spared to continue your sphere of usefulness amongst the various classes of the community whose friendship and respect you have so deservedly acquired.

Signed on behalf of the officers,
JOSEPH D. COPE, Clerk of the Union.
RICHARD THOMPSON, Workhouse Master.
(Dated) November, 1877.

Address of the Medical Officers of the Rathdown Union.

DEAR SIR,—We cannot permit you to retire from the active discharge of your duties in connection with the Rathdown Union Hospital, without expressing to you our deep sense of regret that we should lose the co-operation of one who has worked so harmoniously amongst us for many years past, and of conveying to you the high estimation in which you have been at all times held by us, in the different relations of life, both as a valued physician, and a warm and sincere friend. We are very sensible of the untiring zeal you have exercised in upholding the rights of the profession, and in endeavouring to raise the status and position of your brethren.

Those sentiments are in no wise diminished by the termination of your official relation to the district; and looking forward with hope to a renewal of your health, and to many years of future happiness and usefulness, we are gratified to believe that the cordiality of feeling entertained by us towards you will long continue.

We remain, dear Sir, yours faithfully,

T. L. WHISTLER, M.B.,	WM. RICE, M.D.,
J. LENEY, M.D.,	C. E. MAYNE, M.B.,
J. F. NEWLAND, M.D.,	J. W. BOYCE, M.B.,
J. F. POLLOCK, M.B.,	A. CROLY, M.D.,
J. W. USHER, M.D.,	R. S. O FLAHERTY, M.B.

DR. DARBY'S REPLY.

MR. COPE, AND YOU GENTLEMEN who do me the honour to represent my non-professional fellow officers. Pray accept my gratitude, my heart-felt thanks for the kind feeling you have embodied in the beautifully illuminated address you have just read, and for this very handsome timepiece, which has the twofold merit of complimenting me and of ornamenting my wife's drawing room. Believe me, both she and I will value them as emblems of a friendship which will on our parts continue warm at our hearts so long as we live.

Dr. Whistler, and you gentlemen who represent my professional brothers of this union, will I am sure forgive me if I fail to find words sufficiently strong to give expression to the feelings of pride and gratitude with which my heart is filled by your kindness. "Out of the fulness of the heart the mouth speaketh," but as, when the milldam overflows, the miller is drowned, so when the heart is too full, utterance is choked.

It has been the ambition of my life to stand well in the estimation of those of my own profession, as well as in that of my non-professional friends and neighbours. That I have not altogether failed in this high aim of my ambition, these flattering addresses, this costly and elegant present assure me, and that assurance makes this the proudest, the happiest day of my life.

Gentlemen all, let me hope that as time rolls on, I may prove myself worthy of a continuance of your friendship, and that my resignation of office will not have had the effect of weakening that highly valued tie, nor of causing estrangement between you and me.

Correspondence.

POST-MORTEMS IN WORKHOUSES.

THE following letter has been sent to us on this subject:

[COPY.]

Local Government Board, Whitehall, S.W.,
1st January, 1878.

SIR,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 14th November last, in which on behalf of the Council of the Poor-Law Medical Officers' Association you bring under their consideration the question of allowing the medical officers of workhouses to make *post-mortem* examinations of the bodies of paupers who die in workhouses.

I am directed to state that the Board have communicated with their medical officer, and have carefully reconsidered the subject, and that they see no reason to alter their views, which have already on former occasions been expressed by them upon it.

The Board are of opinion that a *post-mortem* examination should not be made of the body of a workhouse inmate except by the direction of a coroner when holding an inquest, or the direction of the Board of Guardians for any especial, urgent, and particular reason which they may deem of sufficient importance to render such an examination necessary, or at the request of the relatives of the deceased.

The Board also direct me to state that they think that a Board of Guardians would hardly be justified in directing in any particular case that a *post-mortem* examination should take place if the nearest relative of the deceased objected clearly and decidedly to that course.

The Board under these circumstances are not prepared to take the proceedings suggested by the Poor-law Medical

Officers' Association, or to issue any minute or regulation on the subject.

I am, Sir, your obedient servant,
(Signed) HUGH OWEN, Jun.,
Assistant-Secretary.

To J. W. Barnes, Esq., Hon. Secretary to the Poor-law Medical Officers' Association.

MILL ON VIVISECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Knowing nothing of Miss F. P. Cobbe save through her publications, I yet entertain a high respect for her; still, I would be slow to bind myself to all her views and opinions. I feel that Dr. McDonnell, in his address to the Irish Surgical Society ought to have told his audience that her strongly-phrased declaration against vivisection was a wordy and windy plagiarism of a famous and, I think, very blasphemous declaration of Stuart Mill with regard to the quality of God's mercy. I have not his "Life" near me, and can therefore only give the substance of what he said from memory. It was that if it were necessary to be damned for not believing that the nature of God's mercy was not the same as that of man—why, damned he would be.

Yours obediently,

Dec. 15, 1877. M.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. GRIFFITHS.—Communication on "Amennorrhœa" received.

MR. G. R. J.—Quite inexplicable.

DR WILLIAMS, MR. F. S., and DR. REYNOLDS will find the subject of their letters referred to in our "Notes on Current Topics."

MR. HILL should consult the "Nouveau Dictionnaire Pratique," par MM. Bouley and Reynal.

CURIOUS.—1. Not to our knowledge. 2. The gentleman died in February last. 3. You will find this question considered in our *Annus Medicus* for 1877 in the last number; the allied topics are referred to in the same article.

SALICINE.—A correspondent having tried by his own unaided knowledge to determine the origin of this substance, with only partial success, asks for information: We give the definition of Mr. John Moss, F.C.S. He says: "Salicine.—This body is a glucosid, obtained from the bark of the willow. It is a white crystalline powder." During the past year numerous reports have appeared on the use of salicine in acute rheumatism, and judging from these, it excercises almost a specific curative influence in such cases. Dr. Senator, of Berlin, believes that the effect is due to the conversion of most or the whole of the salicine into *salicylic acid* within the body. In endocarditis 20 grains have been given in glycerine and hot water every four hours for three days—afterwards every six hours. In acute rheumatism 5 to 15 grains are given every hour, according to the severity of the case. It is described as "producing no bad effect, patients taking it making a thorough and rapid convalescence," in this respect having a decided advantage over salicylic acid. Salicine has also been recommended in intermittent and malarious fevers. Dr. W. Thomson, of Peterborough, has used it with much success in the treatment of ague; he gives it as a powder in 30-grain doses every two hours, and considers it for this purpose superior to quinine. It is not very soluble in water, but may be given mixed with it or with a little milk.

DR. CORY.—Theological discussions are not exactly suited to our columns.

A CANDIDATE.—We understand that the next examination of candidates for commissions in the Army Medical Department will be held in London on February 11th, and following days. The tenure of appointment is 10 years, after which the army surgeon receives a sum of £1,000 on retirement in lieu of pension. Candidates should send in their names and addresses at once to the Director-General in London.

THE MANCHESTER WATER SUPPLY AND THE LAKE DISTRICT.—Letters have been received in approbation of our article condemning this scheme from—Dr. Griffith, "Utilitarian," "A Manchester Merchant," Dr. Williams, Mr. W. S. Unthank, Dr. T. T., M.D., "A Lover of Nature," Mr. Lever, Mr. Fox, Manchester.

A LATE EAST INDIAN should apply to one of the recognised medical agents for practices and partnerships in this country.

MR. E. M. S.—The modificaction can be procured at Messrs. Krohne and Seseman's, the makers. We think it is a too recent invention to be had second-hand. Lawley and Son, of Farringdon Street, would probably enlighten you on this point.

DR. E. M. B.—We need only say you have our warmest sympathy. We are afraid we cannot further assist you. Corporations are not to be depended on, and gratitude or recognition of merit are rarely met with. The appointment has the appearance of "a job," the successful candidate evidently possessing backstairs influence, or his qualifications and past experience would certainly not have placed him over the heads of those whose claims were, in every respect, so much higher. Were it a public appointment we would really yield to your solicitation and expose the matter; its privacy places it beyond our pale.

DEAR DIRTY DUBLIN.—Thanks for your agreement with our views. Your letter, however, is too strong for insertion.

LIFFEY-ANNA.—Your appeal would be more suited for the *Freeman's Journal*, or other lay journals.

F.R.C.S.I.—Your letter is too long. The sanitary condition of Dublin is not creditable to the nation.

THE COOMBE.—The writer bears testimony to the miserable condition of the tenements in this neighbourhood, so well known to those who attend midwifery cases.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Consumption; its True Nature and Successful Treatment. By Godwin W. Timms, M.D. London: Baillière, Tindall, & Cox.

Aids to Forensic Medicine and Toxicology. By Douglas Hemming, M.R.C.S. London: Baillière, Tindall, & Cox.

Notes on Asthma. By J. C. Thorowgood, M.D. Third Edition. London: J. & A. Churchill.

The Royal London Ophthalmic Hospital Reports. Part II. Vol. IX.

Ovariotomy by Enucleation. By Julius F. Miner, M.D.

The Students' Pocket Book. By Mrs. Garrett-Anderson, M.D. London: H. K. Lewis.

A Compendium of Diagnosis on Pathological Anatomy. By Dr. J. Orth. American Edition by Drs. Shattock and Sabine. New York: Hind and Co.

Sanitary Report of Paddington for the Year 1878.

The Efficacy of Sulphur Fires in Epidemics of Cholera. By Surgeon-Maior Tuson.

VACANCIES.

Balrothery Union, Luck Dispensary.—Medical Officer. Salary, £125. Election, Jan. 19.

Central London Sick Asylum.—Assistant Medical Officer for the Highgate Asylum. Salary, £100, with board and Residence. Applications to the Clerk to the Board, Fitzroy Square, W.

City of London Hospital for Diseases of the Chest.—Assistant Physician. Honorary. Candidates must address the Treasurer by the 26th inst. (See Advt.)

Durham County Hospital.—House Surgeon. Salary, £100, with board and lodging. Applications to the Hon. Sec., the College, Durham.

Hailsham Union.—Medical Officer. Salary, £68, with fees extra. Address the Chairman of the Board of Guardians, Hawkhurst, Kent.

Hants County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board and lodging. Applicants must address Dr. Manley, Knowle, near Fareham.

Keighley Rural Sanitary District, Yorks.—Medical Officer of Health. Salary, £400. Applications to Mr. Brom, Solicitor, Skipton

Limerick Union Workhouse.—Resident Medical Officer. Election, Feb. 2

Northampton General Infirmary.—Physician. Testimonials, &c., to the Secretary not later than January 9th.

St. Mark's Ophthalmic Hospital, Dublin.—Assistant and House Surgeon. Salary, £80, with apartments and allowances, Election, Jan. 21.

Sunderland Infirmary.—Senior House Surgeon. Salary commencing at £80, with board and residence. Applications to the Secretary of the Medical Board.

Thingoe Union.—Medical Officer of Health. Salary, £100. Also Medical Officers to the Second and Seventh Districts of the Union. Salary, £84 for the former, £70 for the latter, both exclusive of the Midwifery and Vaccination Fees. Applications to the Clerk of the Board, Bury St. Edmunds.

Tipperary Union, Grean Dispensary.—Medical Officer. Salary, £100. Election, Jan. 14.

Warminster Union.—Medical Officer for the Longbridge District. Salary, £80, with fees extra. Applications to the Clerk, Union Workhouse, Warminster.

APPOINTMENTS.

ALLAN, J., M.B., C.M., M.A., Senior House Surgeon to the Liverpool Northern Hospital.

BALLANTYNE, A., M.D., F.R.C.P., L.R.C.S.Ed., Physician to the General Hospital and Dispensary for Sick Children, Manchester.

HAMERTON, M. F., M.B., C.M., Medical Officer for No. 4 District of the Mansfield Union.

POYNDER, G. F., L.R.C.P.L., M.R.C.S.E., House Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital.

RAPER, W. A., M.D., M.R.C.S.E., Medical Officer and Public Vaccinator for the Wakering District of the Rochford Union, Essex.

SNADDEN, J., M.B., C.M., Resident Medical Officer to the Pontefract General Dispensary.

STORY, J. B., M.B., C.M., Junior Surgeon to St. Mark's Ophthalmic Hospital, Dublin.

THOMPSON, R., M.D., L.R.C.S.I., Medical Officer to the Workhouse and Fever Hospital of the Urlingford Union, cos. Kilkenny and Tipperary.

WATTER, W., B.A., M.B., Obstetric and House Surgeon to St. Mary's Hospital, Manchester.

Deaths.

BUTTER.—On Dec. 24, at Hazlewood, Upper Norwood, Donald Butter, M.D., Inspector-General of Hospitals, Bengal Service, Retired List, aged 78.

COLLIER.—On Dec. 23, at Chiswick, George Frederick Collier, M.D., aged 78.

DAVIES.—On Dec. 19, at Llanidoes, William Abel Davies, M.R.C.S.E., aged 45.

HAWKER.—On Jan. 1, at 26 White Horse Lane, Stepney, E., Charles Hawker, M.D., aged 59.

TAYLOR.—On Dec. 28, at St. James's Railway Station, Liverpool, suddenly, John Taylor, M.R.C.S.E., aged 70.

WHARTON.—On Dec. 21, at Bedford, George Wharton, M.D.

IRISH POOR-LAW INTELLIGENCE.

THE ABUSE OF DISPENSARY TICKETS IN DUBLIN.

At a recent meeting of the North Dublin Guardians, a letter was read from Dr. A. Speedy, enclosing a communication which he had sent last month to the North City Committee. He complained that a visiting ticket issued to him for medical relief and visiting, and which purported to be signed by Mr. Rochfort, was a good example of the way in which the Medical Charities Act is abused. The father of the patient is a bellows-maker, and has the entire house, rated at £18 yearly, and his wife told him (Dr. Speedy) that she was quite able to pay for medical attendance, but that she was anxious for his opinion. The ticket which he enclosed was not signed by Mr. Rochfort, and on different occasions he had remarked that tickets issued at Mr. Rochfort's establishment were not signed by him, but by his assistant. Such a practice, especially with reference to visiting tickets, was highly reprehensible.

The following resolution had been adopted by the dispensary committee thereupon :—

"It is the opinion of the dispensary committee, that no ticket is valid unless signed by the parties authorised to do so. We consider it necessary to pass the above resolution, as we have had to cancel several tickets to parties well able to pay ; and that a copy of the above resolution be sent to each of the guardians, wardens, &c."

In reference to this question, we may remind our readers that the Local Government Board was not long since applied to for its opinion as to the legality of tickets thus illegally issued, and delivered itself then of a very peculiar decision. A representation was made to them by a dispensary medical officer, that, in his district, medical relief tickets were habitually issued by persons who have no right to give them, to persons who have no right to receive them, and without inquiry as to the competency of the recipient to pay, the tickets having previously been signed *in globo* by the committee-man and left with the potboy for distribution among all good customers of the shop. The medical officer wrote, therefore, to the Local Government Board as follows :—

"In the General Rules and Regulations for the Government of Dispensary Districts, published in 1870, and supplied to us, I find at page 28, under the head of 'Directions for filling up Medical Relief Tickets,' the following :—

"'The ticket and counterpart are both to be filled up *by the person authorised to issue* the ticket, one part to be retained by the person issuing the ticket, and the other to be detatched from the book and given to the applicant for presentation to the medical officer.'

"I therefore pray respectfully that I may have a ruling as to :—

"I. Whether a guardian or a warden can hand over to others the giving way of the public funds by means of such blank tickets, signed by them ?

"II. Is the issue of such tickets by the servants of a guardian, or warden, in the manner described, legal, and is the medical officer bound to attend, and continue attending on such tickets ?"

These are very straightforward questions, and they place the Local Government Board in a very simple position. Either tickets so issued are legal, and the medical officer is bound to attend on them ; or illegal, in which case the Local Government Board is bound to deal with the infraction of its own laws. But the Irish Poor-law Department carefully avoid either horn of the dilemma, for it declared the tickets illegal, but, nevertheless ordered the medical officer to honour them, and intimates distinctly its intention to permit the illegality to continue. Here is the reply :—

"The Local Government Board . . . . . desire to state that the practice of signing blank tickets for medical relief, and leaving them to be afterwards filled up by a person who is not authorised to give tickets, is at variance with the provisions of the Medical Charities Act, and the Dispensary Regulations. . . . . The Local Government Board, however, think, that when a ticket, *duly signed*, is presented to you, you are bound to act on such ticket. . . . . You can, however, bring any such case under the notice of your dispensary committee."

There is one solution of the difficulty, of which it will be well that the efficacy should be tried. It has never been effectually decided whether it is competent for a medical officer to recover his fees from either the issuer or the recipient of an improper ticket. In the case of Woods *v.* Connelly the issuer *was* made liable for the doctor's remuneration, but the case never was brought to a final determination because the judges differed in opinion as to the method of procedure. It is still a moot point whether the recipient of a ticket can be made to pay after the committee has cancelled the ticket, and thereby declared its opinion that he was capable of paying for medical advice.

It is a question legitimately lying within the scope of the Irish Medical Association to decide.

MONTMELLICK UNION.

THE CLONASLEE DISPENSARY—RESIGNATION OF DR. WILKINSON.

A letter was read to the guardians from Dr. Wilkinson, of Clonaslee, resigning his dispensary after thirty years' service.

ARMAGH UNION.

A SUPPOSED LUNATIC.

The chairman read a warrant from the Glasgow autho

rities, for the removal of Francis Cook, aged 23, who had become chargeable to the Glasgow Union, and who had been born within the Union of Armagh.

The Master stated that a "keeper" brought him over in the boat and on to Armagh stating that he was a dangerous lunatic.

The Chairman—Have they power to remove lunatics in that way?

Mr. Winder—I don't think they have.

The Chairman suggested that the matter be brought under the notice of the inspector, and the result communicated to Dublin.

Francis Cook, who was waiting, was brought into the board-room, and, in reply to the chairman, said he had been three years in Scotland; he belonged to Drumbeg; he was put into the asylum beyond and not to the workhouse; he took a little cold and was not able to go in to his work on a Monday morning. He took his breakfast, went out, took a glass, and had not went far when his landlord came after him with some police and lodged him in the asylum.

Mr. Gamble—We have no proof of his lunacy in the documents furnished, and we need not be making a case of him for the union.

The Master—He says he would like to go to his father's; and that he would not stay here unless it were compulsory.

Dr. Roughan, Local Government inspector, and Dr. Riggs, medical officer, examined the man, and both disapproved of his being sent out in his present condition.

Mr. Atkinson suggested that the proper way to dispose of the case would be to get the man into the Asylum at once. If they went the right way about it, it would only be the work of an hour.

ARMAGH UNION.

FEE FOR LUNACY CERTIFICATES.

A MEMORANDUM, signed by two magistrates, was read, to which was appended an account for £1, furnished by the medical officer of the union, for examining the lunatic, Francis Cooke, who was sent to his native place by the authorities from an asylum in Glasgow.

Mr. Gibson—Isn't he in our service, and we pay him; surely he is to examine a person coming into the house?

The Chairman—The usual course is, the dispensary doctor should examine him; but it is better for us under the circumstances to send it forward and see if it will be paid.

Mr. M'Crum—Can we disobey the magistrates' orders?

The Chairman—Let us put "approved" on it, and let it be put on the minutes.

Entered accordingly.

MULLINGAR UNION.

AT the usual weekly meeting of the guardians it was proposed:—"To take into consideration a resolution of the Mullingar Dispensary Committee, recommending the doctor's salary to be increased."

Mr. Nulty said that at a meeting of the Dispensary Committee, Dr. Kelly applied for an increase to his salary, in consequence of extra duties he had to perform since his appointment, a return of which he had furnished, and also that his salary was lower than that received by Dr. Stokes. After a patient investigation into the matter, and an examination of the books, the committee unanimously resolved in increasing his salary by £30 a year.

The Chairman inquired how long Dr. Kelly was appointed to his present office.

Mr. Nulty said he thought the doctor was appointed to his present office about eighteen months ago.

The Chairman said it was rather soon for him to apply for an increase of salary.

Mr. Lemon remarked that if an increase of salary was now granted to Dr. Kelly, the other medical officers of the union would be looking for a like increase.

Mr. Glennon—Dr. Kelly had more than double the duties to perform than any other medical officer in the union.

Colonel Cooper moved as an amendment that £10 a year be added to the medical officer's salary.

Mr. Sullivan, in order to meet the feelings of the Board, proposed that the salary be increased £20 a year.

Mr. Nulty withdrew his resolution in favour of Mr. Sullivan's amendment, with a view to the unanimity of the Board.

The Board then divided; for an increase of £20, 14; for £10, 9.

NAAS UNION.

KILDARE DISPENSARY.

THE Local Government Board transmitted a copy of a letter which they have received from Dr. Kehoe, medical officer of the Kildare Dispensary, relative to a proposed change in his residence.

Dr. Kehoe stated that he was building a residence within a quarter of a mile from his present residence in Kildare, and purposed building a dispensary attached to the residence.

The Local Government Board replied "that the matters in question are entirely for the consideration of the Board of Guardians and the Committee of Management." With regard to the proposed change in the dispensary, the committee did not approve of it.

OMAGH GUARDIANS.

SINGULAR SANITARY CASE.

THE Rev. J. R. Dill brought under the notice of the Board by letter, the case of the woman Hutchinson and her four children which had already been before the Guardians. It appeared that notwithstanding being possessed of sufficient means the woman still continues to keep her house in a most filthy and dilapidated condition, and her children in a state of starvation.

Mr. Hugh Graham stated that the lives of the children were in danger.

Major Buchanan said that on the last day the case had been before the Board it was arranged that the woman should be examined by the doctor so as to have her removed to the asylum.

Mr. Crawford, relieving officer, stated that the doctor would not certify that the woman was a dangerous lunatic.

Mr. Anderson said that Dr. Marshall would certify that the woman was a lunatic but not a dangerous one.

The Chairman stated the Board of Guardians could not interfere further. She would be prosecuted as a sane woman for starving her children. It would be quite enough for the Guardians to express an opinion when the case came before them.

Mr. Greener thought that a second medical man might be employed in the case. If the woman was a lunatic at all, why not send her to the asylum?

DR. LOVE'S SUPERANNUATION.

The Chairman intimated that the present was a special meeting, and that the first matter to be disposed of was Mr. Galbraith's motion, proposing to grant from the rates of the Union, a superannuation allowance of £125 17s. 10d. per annum to Dr. W. S. Love, late Medical officer of the Omagh Dispensary District. The Chairman read the medical certificates, showing the condition of Dr. Love's health and his physical inability to continue his dispensary duties without endangering his life.

J. S. Galbraith, Esq. in proposing his motion said—I hope that no difference of opinion will arise upon this question which is really not a question of favour, but one of simple justice. I could not describe in sufficiently strong

language the profound regret felt, not only by his patients, but by all who know him—(hear, hear)—at Dr. Love's compulsory resignation, and the regret is enhanced by the melancholy occasion which has led to it, namely, declining health. Although I conceive that no words of eulogy are required to fortify Dr. Love's claims, I cannot forbear giving my testimony (since I have had opportunity of observing it) to his unvarying attention to his onerous duties, ready at all hours to attend to the call of the humblest in his extensive district, and I am sure others could give corroborative testimony since the date of Dr. Love's appointment, twenty-three years ago. I know that his name is treasured as a household word by his patients, and their common expression "the sight of him does me good" speaks volumes as to his kindly sympathy, which the poor so much appreciate, so different from the callous and perfunctory way in which, I fear, in too many cases their wants are looked after.

Mr. Young seconded the motion.

Mr. J. Moore proposed as an amendment that Dr. Love receive no superannuation allowance, and said: The friends of Dr. Love feel grieved at the cause of his retirement, but they have at the same time the satisfaction of knowing that his sickness is "not unto death," inasmuch as he is still able to hold other offices——

Chairman — A lucrative position on the militia. (Laughter.)

Mr. Moore continued—Now the law allows the Guardians to give pensions in *certain cases*, but I hold that Dr. Love's case is not one of those referred to. If I understand it aright this law was made for the benefit of doctors in poor districts, where there was little or no private practice, and where, if failing health necessitated the doctor's retirement, the Guardians could grant a pension of one-third or one-half of the salary, as the case might be. But the law never contemplated giving a coach-and-four, or going nearly to that length. (Laughter.) Another case in which it is proper is where the doctor is permanently affected but that does not apply to the case before the meeting. And yet if Dr. Love was never able to cross his room door the amount here sought to be given him could not be greater. He has already been well paid for his services; he had received some £4,000 out of the rates during his time, and in other respects there are reasons why a pension should not be given. I think it absurd in this instance to give £125 17s. 10d. out of the poor rates, and it could not be very pleasing to her Majesty, did she know it, that a man in her service was receiving a pension out of the poor rates.

Mr. Buchanan, in proposing another amendment, said—I think it will meet the views of the meeting if we come to some sort of compromise. I quite agree with Mr. Galbraith in every word that fell from him with reference to the character of Dr. Love. We have the certificates of the physicians, and the fact of Dr. Love's long service—for the space of 23 years. On these 23 years I am satisfied to rest the case. I say the man against whom no complaint has been made for 23 years, and who has so satisfactorily laboured for that time amongst the poor of the district, I say that it is not now for us to thrust him from us. I pay as much personally to the rates of the Union as any one present, but if I paid twenty times as much I would not grudge this, if it were only to show how we esteem Dr. Love. Perhaps the amount stated by Mr. Galbraith is too much—certainly not more than Dr. Love deserves—but it may be more than we should give. I would propose £100, being two-thirds of the pay without emoluments.

Mr. R. S. Clements supported Mr. Moore's amendment, negativing the motion. He said—In looking over the words of the act I find that if a superannuation is given it must be "by reason of permanent infirmity of body or mind, or old age." I think Dr. Love is not in the category of any of these. Although it has been alleged that his health is impaired, I have my own opinion. Of course it is hard to doubt the doctors, but from past experience I have reasons for what I state. I cannot give a milder term to these certificates than that they are fallacious and misleading. We can hold our own opinion with regard to doctor's certificates as they are given to us. I think such documents should be sworn to as they are in a court of justice, and not be given as has heretofore occurred, without the doctor ever having seen the patient. These men took office without expecting superannuation and compassed sea and land to get into their posts. They were then satisfied and if they are now refused they cannot be disappointed. I would refer now to the last dispensary election, when a doctor informed me that if appointed he would agree to sign a paper that he would not expect or desire a superannuation allowance.

No other amendments were made.

The votes of the Board were then taken on the motion.

For £100 a year, 24. Nothing, 19.

The amendment proposing a superannuation of £100 was declared carried.

Subseqently Mr. James Moore handed in the following notice of motion :—"Take notice that I will move this day two weeks that the resolution grantiug a superannuation allowance to Dr. Love be rescinded on the ground that he holds other laborious offices (surgeon of Tyrone Militia, &c., and the recruiting from town to town in the said county), and his health is good and would still be able to hold the Omagh Dispensary. That the Local Government Board be requested not to sanction said resolution."

The Chairman informed the Board that a sealed order from the Local Government Board had arrived, for the payment of £100 per year to Dr. Love, being the superannuation allowance proposed by the Guardians.

Mr. Clements inquired whether it was a sealed order or a sanction.

The Chairman produced the document and stated it was a sealed order.

The Chairman further intimated that the present was a special meeting to consider the motion of Mr. James Moore, viz :—"That the resolution, granting superannuation allowance to Dr. Love be rescinded, on the ground that he holds other laborious offices—surgeon of Tyrone Militia, and the recruiting from town to town in said County—and his health is good, and would still be able to hold the Omagh Dispensary." He supposed that as a sealed order had come, Mr. Moore would drop his motion.

Mr. Moore said he did not intend to drop the motion, and was proceeding to propose it, when

Mr. Mackay rose to a point of order, and said Mr. Moore could not proceed with his motion in the face of the Local Government Board's sealed order.

Mr. Clements held that the document was no sealed order, only a sanction

Mr. Black referred to the Barrister's decision in Dr. Robinson's case. He had ruled that a similar document was an order, and granted a decree by it. The Local Government Board at anyrate would not withdraw the order.

Mr. Clements urged that the motion be received—if there was a majority in favour of it, the matter would go before the Court of Queen's Bench.

After some further observations,

The Chairman said the Board would merely stultify themselves in moving to rescind a sealed order of the Commissioners. They tried to rescind one before, but it was of no use. He declined to put the motion.

Mr. Clements then proposed that the Chairman leave the chair and that his place be taken by the Vice-chairman, and that the motion be put.

The Chairman said that motion was as illegal as the other and declined to put it.

Mr. Clements protested against the action of the Board, and the matter dropped.

MEDICAL WITNESSES IN CRIMINAL CASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been a Crown witness at the winter assize

just concluded at Galway. To reach Galway I had travel 150 miles, yet the Crown solicitor informed me that *it was not in his power* (without a special order of the Court) to pay me more than if I was attending assizes in my own county town, a few miles distant. I would ask you if you consider two guineas a-day, with fifteen shillings hotel and railway fare, a sufficient remuneration for travelling backwards and forwards a distance of 300 miles, and giving evidence on behalf of the Crown? As I understand that these winter assizes are, owing to the facility of getting verdicts, to be continued, the matter might, I think fairly claim the attention of the Irish Medical Association.

Faithfully yours,
JUSTICE.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF DECEMBER, 1877.

DECEMBER 18th.—Fahie, Chas. Joseph, 23 Leinster Square, Rathmines, co. Dublin, Lic. R. Coll. Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

18th.—White, Thos. George, Clonevan, Gorey, co. Wexford, Lic. 1877 and Lic. Mid. 1877 K.Q.C.P.I., Lic. R. Coll. Surg. Irel. 1877.

20th.—Gray, John, Bridgnorth, Salop, Lic. R. Coll. Surg. Irel. 1875.

24th.—Dedrickson, Robert Forrest, 1 Rathmines Terrace, co. Dublin, Lic. R. Coll. Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

31st.—Thompson, Robert Norman, Kilquaide, N. T. ‖Mt. Kennedy, co. Wicklow, M.B. Univ. Dub. 1877.

31st.—Donovan, Robert Edward, Galtie Lodge, Galbally, co. Limerick, M.D. Q. Univ. Irel. 1877, Lic. R. Coll, Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

31st.—O'Connor, Patrick, Cahirowen, Athenry, co. Galway, M.D. 1877 and M.Ch. 1877. Q. Univ. Irel.

31st.—Davison, James, Clonmany, co. Donegal, Lic. R. Coll. Surg. Irel. 1877, Lic. R. Coll. Phys. Irel. 1877.

31st.—Westley, George, 21 Trafalgar Terrace, Monkstown, co. Dublin, Lic. R. Coll. Phys. Irel. 1877, Lic. 1877 and Lic. Mid. 1877 R. Coll. Surg. Irel.

31st.—Mackenzie, Wm. Gillespie, Lisburn, co. Antrim, Lic. R. Coll. Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

31st.—Brereton, John Thomas, Dronfield, Sheffield, Lic. K. Q. Coll. Phys. Irel. 1877. Lic. 1877 Fell. 1877, and Lic. Mid. 1877 R. Coll. Surg. Irel.

31st.—Walsh, John Edward, Morlinstown, Kilmallock, co. Limerick, M.D. 1877 and M.Ch. 1877 Q. Univ. Irel.

31st.—Dingenan, John Joseph, Belturbet, co. Cavan, Lic. R. Coll. Surg. Irel. 1876, Lic. 1877 and Lic. Mid. 1877 K. Q. Coll. Phys. Irel.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING DEC. 29, 1877.

Total registered deaths in Dublin and suburbs* ... 163
Ten years average of same week 169

Decrease of mortality below average 6

10 weeks ratio of deaths Rathmines 14·6 per 1,000
" " " " Donnybrook† 23.9 "
" " " " Blackrock 21·7 "
" " " " Kingstown 19·7 "
" " Entire Dublin District 26·9 "
COMPARATIVE RATIOS—London ... 25·9 "
" " Glasgow ... 23·2 "
" " Edinburgh ... 22·3 "

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 30, which was also the average number in the corresponding week of the previous ten years. The deaths from these causes include 4 from fever (3 typhoid and 1 simple continued fever), 10 from measles (including those of two women, aged respectively 29 and 45 years), 1 from small-pox—that of a man aged 34 years, a resident of Meath Street District, who died in Cork Street Hospital—3 from whooping-cough, 2 each from croup and dysentery, 1 each from diphtheria, diarrhœa, &c.

Seventeen children died from convulsions.

Bronchitis caused 33 deaths, and pneumonia or inflammation of the lungs 5.

WATERFORD.—The Registrar remarks "Measles still prevalent."

TABLE *showing for* EIGHT LARGE TOWNS, &c., *the* AREA, *in Statute Acres; the* POPULATION *in* 1871; *the* ANNUAL RATE OF MORTALITY *per* 1,000 *Inhabitants represented by the Number of Deaths registered during the Week ending Saturday, December* 29*th*, 1877; *the Total Number of* BIRTHS AND DEATHS *registered during the Week with the Number of* DEATHS *at certain Ages, and from* SEVERAL CAUSES, &c.

ON THE INDICATIONS FOR THE USE OF THE TREPHINE

DERIVED FROM CEREBRAL LOCALISATION AND THE RELATION OF THE CRANIUM TO THE BRAIN. (a)

By DR. SAMUEL POZZI,

Professeur D'Anatomie a la Faculté de Medicine; Interne Laureat des Hôpitaux de Paris; Membre de la Société Anatomique et de la Société d'Anthropologie.

(*Continued from page 532, last volume.*)

Do we wish to find out the motor centre of the arm? Place the crown of the trephine in front, of this line, *above*, if we believe Ferrier; towards the middle, if we hold with Hitzig. Do we wish to discover the centre of the inferior member? Apply the trephine, behind, the Rolandic line, and *above*, according to Ferrier—in front and *above* according to Hitzig.

The centre of the muscles of the face are immediately in front of this line, towards its middle, according to the same author.

But if we refer to the experiments of Ferrier on the monkey, it is placed more anteriorly on the second frontal convolution, and to reach it we must advance two centimetres from the middle of the Rolandic line. Two centimetres in advance of the summit of this line, we must seek the centre of the movements of rotation of the head and neck, if we accept the conclusions of the English physiologist; and I have previously shown why they appear to me preferable to the results of Fritsch and Hitzig.

Without going so far as to affirm with M. Lucas Championnière (b) "that we can as easily succeed as we apply a ligature to an arterial trunk," we may say with him *that, given a lesion of a cortical centre*, the surgeon is in a position to open the cranium at a fixed point, and fall just on the seat of the lesion; but we must be cautious. This proposition, which at first sight has the appearance of solving the problem, contains, in reality, only its announcement set forth in that part of the phrase which I have *italicised*.

And yet this author does not hesitate to maintain "that he has reached and solved the problem of the employment of cerebral localisation as a guide to the operation of the trephine." (a) Elsewhere he congratulates himself "on the certainty brought to an operation, up to the present so so little directed." (b)

Virtually, the "doubts and insufficient ideas on functional localisation," do not detract in the eyes of this daring surgeon, from the benefit we may derive from cranio-cerebral topography. He believes that he has fixed on the cranium the exact limits of a motor region, "the centre of which, in difficulty, the operator may touch almost with certainty."

He has not obtained any results; but that does not signify.

M. Lucas Championnière is not stopped by "details so trifling." He daringly proposes to multiply the area of the trephine. "You can," he says, "cover in an operation all the region, and still have a successful operation."

What is the extent of this motor region?

According to M. Lucas Championnière, it would appear to be eight centimetres by three, that is to say, he would consider as a good operation the creation of a breach of twenty-four centimetres square in the cranial walls.

Has M. Championnière yielded to the reminiscence of Henry of Nassau, who certified that his surgeon had judiciously applied twenty-five heads of the trephine.

These are *amusements of princes*, which, it seems to me, are too dangerous to be repeated. Nay, more, the loss of substance necessarily following the engagement of all the motor regions in the operation, is much greater than M. Lucas Championnière thinks. Look at the limit he assigns to it. In front the limit of the parietal; behind, the

(a) Translated from *Les Archives Générales de Médicine*, 1877, by Thomas M. Dolan, L.R.C.P. Ed., and revised by the Author.
(b) *Journ. Pract. Med. and Surg.*, February, 1879, p. 57.

(a) *Journ. Pract. Med. and Surg.*, February, 1877, p. 59.
(b) "Proceedings of Surgical Society," 14th February, 1877 p. 123.

parietal boss ; above, the longitudinal sinus ; below, the third frontal convolution.

Now, in verifying the dimensions thus obtained on six cranial caps, on which the convolutions were marked, after the method of M. Broca (*a*) I have found that though the latitude of this region was, as indicated by M. Championnière (81 millimetres)—the breadth, that is to say, the distance between the limit of the parietal in front, and the parietal boss behind, was considerably greater, nearly eight centimetres (78 millimetres).

Again, in taking this measurement, I commenced much in front of the posterior limit of the motor centre, occupying the totality of the superior parietal lobule. With still more reason, I have not included the centre situated on the *pli courbe*, a centre which ought logically to find a place in the motor region.

But even without this last correction, theoretically necessary, we see that the motor region, as understood by M. Lucas, is not only twenty-four, but sixty-three centimetres square.

It is needless to insist on the consequences resulting from this change of figures.

However "prodigious may be," and according to this author, "the attenuation brought by antiseptic dressings to the gravity of the operation," certainly any one would hesitate, at covering such a surface with the trephine.

When we read the remarkable discussion on the trephine which occupied, in 1867, many sittings of the Chirurgical Society, we see that in the midst of the grave difficulties which surround this formidable question, there is one especially in presence of which a surgeon must confess himself perfectly powerless.

In cases of persistent hemiplegia, even without exterior lesions, M. Le Fort has advised the trephine.(*b*)

"At what point would you apply it," asks M. Trelat, "as you are acting only at hazard when you have no external trace ?"

To this objection M. Le Fort replied : "I will operate on the side opposed to the paralysis, and I will search for that lesion." (*c*)

Seek the lesion, without anything to guide the instrument, with the probability of being obliged to stop, perhaps, after many useless applications, rather dangerous to the patient, for if made not direct on the seat of the injury they increase the chances of encephelomeningitis. In this prospective is there not something to make us hesitate, and to arrest the hand of the most daring surgeon ? and if he decides to interfere under the conviction that the patient will inevitably die if not relieved, with what ardour would he not receive any means offered to clear up his uncertainty. (*d*) In fine, if in place of a feeble light we promised him a shining one, capable not only of guiding him in cases particularly difficult, but still more of precisely pointing out the place for intervention, only after the study of symptoms, with what enthusiasm would not the surgeon be seized in face of this new era opened to the treatment of wounds of the head ? This in effect is the bearing of recent researches.

Can we put above, or even simply on one side, the exterior guides (fractures, depressions, wounds, local signs of contusion, or inflammation) which have, up to the present, alone marked the place for surgical intervention, indications derived from within functional signs, such as would be sufficiently pathognomonic to supply in the absence of a local lesion, or, when existing, to enter into the balance with it, and modify in some measure, the point where we design to apply the trephine ?

If man, when injured, afforded the same phenomena as we have derived from animal experiments, the surgeon would then assuredly derive valuable aid, from our knowledge of cerebral localisation.

On the appearance of derangement of inability in any group of muscles, we might, like the members of the Royal College of Physicians of London, who saw Ferrier act on a monkey with the electric current, know exactly what particular motor centre was touched.

Unfortunately, things are not as clear at the bed-side of the patient as in the laboratory, because we are there not masters of the perturbating phenomena.

The preceding remarks apply to recent wounds, and cases demanding the primary use of the trephine. If we analyse the observations, we are struck by the extent, the diffusion of the symptoms, sometimes even by their erratic nature, without doubt due to the disturbance produced by the concomitant concussion. We very exceptionally find convulsions localised, or paralysis circumscribed—monoplegia. If, in a manner more or less rapid, hemiplegia or partial convulsions often appear, such symptoms must be pronounced unpathognomonic. It is true, derangements of motility of this character have been rarely observed, but they have been consequent, upon injury to the temporal (*a*) and occipital regions, (*b*) which are not in immediate relation with the motor centres, and they have followed in a positive manner. I could multiply quotations relative to facts of this kind, but I prefer to rapidly analyse, from this point of view, a very remarkable case lately presented to the Surgical Society of Paris.

It concerns a man, who had received a blow from a spent ball, which carried off the superior part of the bell of the ear, whilst the squamous portion of the temporal bone lay bare at the bottom of the wound. The patient, at the desire of his relations, went on foot to their house, but arriving there he fell heavily on the floor, unconscious, and Dr. Uhlmann found him in that state when he called. He observed convulsive movements taking place from time to time in different parts of the body, and particularly in the lower extremities.

We must carefully notice this peculiarity. If the trephine was applied, at that moment, according to the theory of the motor centres, the top of the fissure of Silvius, about five centimetres behind the bregma, would have been the point for application. During the following days, paralysis, of the right side and of the face, with aphasia, supervened. Did this suggest the use of the trephine at the top of the third frontal convolution, at the antero-inferior angle of the temporal ?

A little later on, derangements of the movements of the eyes, and on the left side prolapse of the upper lid, external strabismus and dilatation of the pupil, came on. Should attention be directed to the *gyrus curvis* on the right side ? It is not probable that these ideas sprang up to disturb the decision, or to cause the hand of the Mascara surgeon to tremble. He simply trephined at the top of the seat of fracture, viz., on the temporal. Some minutes afterwards the patient opened the left eye, "the prolapse of the right eyelid disappeared," the right hand, paralysed up to that time, showed signs of movement, and he finally recovered, in defiance of all theory.

But I must differentiate ; it is not impossible to explain such phenomena ; it is sufficient to admit that in primary symptoms, or in those occurring early, a great part of them may be attributed to complex lesions, at a distance from the seat of injury.

I am now only dealing with recent wounds, as affording indications for the primary use of the trephine. Cir-

cumstances indicating its use at a later period, are much more exempt from disturbing phenomena.

Lesions which produce complications (abscess, exostosis) are evolved slowly, and isolatedly, and their effects have consequently a simplicity which brings them into comparison with the results of experiment. May this resemblance be pushed so far, that the results, obtained in the laboratory, may be applied in similar cases to pathology? It might certainly be so, if in the absence of impossible experiments on similar subjects, indirect experience, which has so often assisted clinical observation, could be utilised, and if we had established in man the certain existence and exact topography of the motor centres, already fixed in animals. Unfortunately, up to the present, one centre alone complies with this indispensable condition, viz., the centre of language; the third left frontal convolution, which it would not be unbecoming to call the "convolution of Broca." This is the only region of the cerebral surface, injury to which affords us a sufficiently sure diagnosis, so that guided only by rational signs, we may seek it.

On a memorable occasion M. Broca opened a purulent collection which had slowly formed at this point. A man, aged 38 years, admitted on the 27th June, to the Hospital of La Pitié, had received on the previous night a kick from a horse, on the fronto-parietal region, causing a contused wound with denudation of the bone. Slightly stunned by the blow he yet did not lose consciousness, and had not even fallen; he walked to his own house, and on the following morning walked to the hospital.

Broca diagnosed that the denuded part, on which there was no line of fracture, corresponded with the parietal on its anterior border. For the first few days the wound went on well; there was no fever, the patient was not confined to bed, and cicatrisation was slowly proceeding, when erysipelas occurred on the 11th July, lasting ten days.

On the 24th July, twenty-nine days after the accident, he passed a good day.

25th. Morning restless, slight cephalalgia.

26th. Vomiting.

27th. Aggravation of symptoms; temperature 38°; pulse 84.

The patient did not reply to any questions, and the dressers thought he was deaf; when interrogated he either did not reply or used the same phrase, "that is not bad." It was evident he understood what was said to him, as when requested he pressed the hand, opened his mouth, or put out his tongue. From these symptoms it was clear, that the faculty of language was affected, and M. Broca diagnosed some alteration in the third left frontal convolution.

On the succeeding mornings, new and increasing symptoms developed; paralysis of the face with deviation to the left, complete paralysis of sensibility of the two right members, with incomplete paralysis of motility. The short, but decisive course, anterior to paralysis, during which alteration of the faculty of language, coinciding with conservation of the intelligence, had been clearly observed, denoted some alteration of the third left frontal convolution. The totality of concomitant phenomena, and the evolution of symptoms, indicated an abscess. Broca resolved on allowing it to escape by the aid of the trephine, which was applied at the point I have previously indicated, and as soon as the surgeon had opened the bony shield, a large quantity of creamy pus flowed out. To assist the discharge, a second application was made above the first, but encroaching a little on it so as to make only one opening. The external surface of the *dura mater* appeared intact. An hour after the operation, the patient, who had been in a state of *coma*, recovered consciousness; he replied by signs to his name. He did not speak, but made attempts at doing so, and gave several indications that he understood the questions put to him. Some fluid was offered, he took the glass in his left hand, and carried it to his mouth. This amelioration was, unfortunately, not of long duration. At 4 p.m., the operation being finished, at 11 a.m., he relapsed into a comatose state. Two hours after, M. Broca made an exploratory puncture into the dura mater. The autopsy confirmed the exactness of the diagnosis, already verified during the operation. At the point where the trephine was applied, and there only, the internal surface of the *dura mater* presented a dark colour, and the parietal arachnoid was joined to the visceral by some soft adhesions; moreover, the pus infiltration, starting from the fissure of Silvius, extended along the vessels on the external surface of the neighbouring convolutions. The third frontal convolution, was adherent to the meninges, red, inflamed, and softened; in a word, lesions of diffuse meningo-encephalitis existed, having their point of departure from the abscess formed between the bone and *dura mater*. In effect, the first organ manifesting disease was the centre of language, situated directly under the abscess. M. Broca, in his observations on the case I have just analysed, remarks, the trephine was applied too late. "The abscess, though relieved, had already produced irreparable complications, and thus only a temporary amelioration was obtained, and the patient succumbed to diffuse meningo-encephalitis, which nothing could arrest." I have only presented a *resumé* of this very excellent case. It is, up to the present time, the only real application made to the therapeutics of surgery, of our knowledge of localisation, and of the cranio-cerebral topography. The observations, which have been recently offered at different sittings to the attention of the members of the Academy of Medicine, and the Chirurgical Society, though worthy of interest, have not quite a similar bearing. I shall first give an analysis of the cases of MM. Proust and Terrillon, and I must acknowledge their kindness, in favouring me with a complete copy of their observations for this purpose.

On the 8th October, 1876, a young man received on the left side of the head, a violent blow from a sword bayonet; there was abundant hæmorrhage, and loss of consciousness ensued, lasting a quarter of an hour. On the following morning, for a short time he was again unconscious, and he complained of heaviness in the head, but there were no bad symptoms, either as regards speech or movements of the members. His condition was very satisfactory up to the 19th or 20th of October, about eleven or twelve days after the injury, when he was attacked with embarrassment of speech, weakness of the right upper extremity, and facial hemiplegia; these symptoms progressively increased without notable cephalagia or vomiting. On the 26th October, a crucial incision made at the top of the wound, revealed a quadrilateral depression, about the size of a square centimetre and a half, and the fragment was so directly driven in, that the external table appeared on the top of the internal table of the adjoining part.

"In the presence of a depression of this nature," observe the authors, "of the concordance existing between the paralytic symptoms and the fracture of the cranium, in the absence of fever, cephalalgia, and of convulsions, there was one therapeutical indication evident."

The use of the trephine was required, and it was employed the following morning. The crown was applied behind and above the depressed part, but touching slightly upon it. Three moderately large fragments and many small ones were lifted up and removed. When the deepest one was taken away some drops of pus mingled with blood flowed out. The surface of the *dura mater* was red and congested; phenic acid was applied. The operation was scarcely finished, when they were astonished at the "almost instantaneous amelioration. The facial paralysis was not very sensibly diminished, but the paralysis of the arm was much less intense, and of this they were assured by making him press their hand. The aphasia was also improved; he counted from 90 to 97, which he could not previously do." The following days there was greater improvement, interrupted for a short time by erysipelas.

When the case was published the aphasia had disappered; there was only a slight stammering which he had from childhood; the right arm had acquired almost its

normal force; the facial deviation was nearly imperceptible.

We have here a very interesting case, illustrating the use of the trephine in depression of the cranium, which causes complications, about fifteen days after the injury.

This evolution belongs to a numerous and well-known class of wounds of the head. The judicious treatment applied does not remove it from its classic bearing, for proof I need only refer to the discussion that took place at the Chirurgical Society. The opinions expressed by MM. Broca, Deguise, Perrin, Le Fort, Legouest, Trelat, are in agreement on cases of this nature. The knowledge of cerebral localisation did not direct the surgical procedure adopted, or point out the place for operation. The crown of the trephine was applied, on rational principles, at the top of the depression. MM. Proust and Terrillon, by a laborious method I need not now enter on, fixed with almost certainty on the injured convolution, the ascending parietal, at the top of the third frontal convolution. Now, if this point corresponds with the motor centres of the upper extremity, it is removed from the one, injury to which produces facial paralysis and aphasia.

These symptoms, though existing in the patient, did not induce the surgeons to increase the size of the wound occupied by the trephine, in the direction pointed out by the theory of localisation. They were guided by the indications furnished by the external injury, as their ancestors would have been, and I may say they could not have done better, as the result proved. Scarcely was the case of MM. Proust and Terrillon brought under the notice of the Academical Tribunal (Nov., 1876) than M. Lucas Championnière (*a*) redirected their attention to a case of his own which had been first published in a thesis (Paris, July 6, 1876). The principal features of his observations I shall abstract.

A man, aged 20, was brought to the hospital Lariboisière, on the night of the 15th or 16th Nov., 1864. He was in a state of profound stupor, from which, in the morning, he was roused with difficulty, by stirring him very forcibly. Motion of the right upper extremity was partly abolished, and aphasia existed.

In his communication to the Chirurgical Society, M. Championnière says: "This man had some signs of a blow on the top of the left parietal boss."

He was more explicit on this important point in his thesis. "There existed some subconjunctival ecchymosis on the external side of the bulb of the conjunctiva. On examination of the cranium, on the left side of the shaved head, was a small wound of about one centimetre and a half, perfectly dry. Such a wound as might be made by a knife. No swelling or effusion around. Pressure did not excite any pain, and no inequality was established."

On the evening of the 28th November, convulsive attacks ensued, repeating themselves many times during the following days. The convulsions did not affect the paralysed members. On the 23rd, seven days after the accident, the symptoms were much more aggravated. M. Lucas Championnière adds:—

"Relying on an analysis of the preceding symptoms, on the consideration of the epileptic attacks supervening on the limited hemiplegia, I suspected the existence of fracture of the internal table, with splinters and effusion of blood, compressing and irritating the brain and its membranes. I then resolved on the use of the trephine.

"I made an incision in the skin *just round the small wound*, I find a small depression on the bone, I detach the periosteum with a knife, and find the depression of the skull exists in front. The depression is not large, but the fragments are multiplied and solidly entangled one upon the other. I made an incision in such a way as to form a half T, and find the whole fracture; I denuded with care the bone, and apply the trephine so as to leave a bridge of about one millimetre between the crown and fracture. I raise with the forceps the small osseous bridge and the fragments. At the bottom of the wound, I see blood effused on the meninges, and in the blood a detached splinter implanted in the dura mater, which I extracted with some difficulty."

The paralysis disappeared four days after; the aphasia on the 14th day, and a complete recovery resulted. M. Lucas Championnière, in his thesis, and in his communication to the Chirurgical Society, endeavours to show that he trephined, according to the works of Turner, at the top of the ascending frontal convolution.

This appears probable, but the important point for us to determine is whether this theory alone was of use to the surgeon. Now in this point of view—the benefits to be derived from theoretical ideas for operative intervention—the two cases I have related afford us instructive food.

They are only separated by some accessory details. On the patient of M. Lucas Championnière the trephine was used to remedy *primary complications*, whilst in the case of MM. Proust and Terrillon it was employed for *secondary complications*. The latter recognised an evident depression, whilst M. Lucas Championnière had to deal with an inappreciable deformity, covered by hair, and did not deem it necessary to make an exploratory incision which would probably have revealed it. But, though ignorant of the depression, he suspected fracture of the internal table.

Are not the cases comparable with these two exceptions? In both cases the use of the trephine was indicated, according to ideas habitually held.

In both cases the operator was guided by a wound, nay, more, by a fracture. In both cases the views relative to localisation, and cranio-cerebral topography have not been of any real help as therapeutical indications. If they presented themselves to the mind of the operator when about to apply the trephine, they could only corroborate the elements of appreciation, already sufficient of themselves.

Shall I say, then, that these theories are without interest to the surgeon?

Such are not the conclusions I desire to arrive at, though it is necessary not to rely too much on certain imprudent declarations. My only desire has been to show that we ought not to adopt novelties, and consider as progress already accomplished by surgery, what is still only the relation of new materials furnished by pathology to the physiology of man.

We must humbly become convinced of this. In the precarious state of our actual knowledge it is not physiology which enlightens clinical medicine, but clinical medicine which enlightens physiology.

We must observe a medium course, and beware of a hasty confidence which may lead to cruel deception; whilst we also guard against a culpable indifference in the face of progress in the way of accomplishment. The true clinician ought not to be indifferent to anything which tends to advance science; although the immediate application of badly-supported theories is not yet possible, they should not be neglected. For some time they may perhaps only serve to enrich our *memoires;* but the day will come without doubt—the history of all scientific progress offers us a sure guarantee—when they will take a more elevated place in the art of healing. Then, but then alone, the surgeon, in place of simply presenting his failures or successes as "contributions to the study of cerebral localisation," may be able to inscribe the legitimate and ambitious title:—

"The Use of the Trephine guided by Cerebral Localisation."

(*a*) *Journal of Practical Medicine and Surgery*, February, 1877, p. 56. Sitting Acad. of Med., 9th January, 1873. Proceedings of Surgical Society, tome iii., p. 119, Meeting of Society, 14th February, 1877.

It is understood that by the will of the late Mr. John Freeland, who died recently at Nice, the Western General Infirmary of Glasgow, becomes entitled to a legacy of £40,000, payable within a year from this date, which is to be applied in the erection and equipment of an additional wing to the institution.

NOTES FROM PRIVATE PRACTICE—CASES OF AMENORRHŒA.

By Dr. G. de GORREQUER GRIFFITH,

Senior Physician to the Hospital for Women and Children, Consulting Physician-Accoucheur to St. Saviour's Maternity.

The following cases are not devoid of interest :—

Miss H., an Irish lady, came to consult me about the suppression of the menses. She is in height above the average, is of large build, though not by any means of a masculine development ; the complexion is dark, the hair is dark-brown, the eyes are of the same hue, the cheeks are full, plump, and with a delicate blush upon them, the lips are likewise full and of the same delicate tint, and the teeth are white and good, showing that there is no constitutional weakness ; the chest is well-proportioned, and the breasts well-developed ; the hips are in keeping with the dimensions of the frame ; altogether the body is well-set and well clothed everywhere with fat, so that there is no evidence of want of condition.

History.—All her family are healthy and very strong, and she herself has always enjoyed the best health, nor can she recollect any illness happening to her, until the present ailment occurred. She always had a ruddy colour in her cheeks, and it is only since this illness that she has lost it, and that the tint of delicacy has made its appearance. About four months ago she was unwell, and while in this state "was greatly frightened, so much so, indeed, that she felt a shock all over her, as if she had been electrified, and was conscious of a great change in her system." The menses seemed to be immediately checked, to be dried up at once, she was "completely paralysed with fear and utterly prostrated." Not wishing to consult a medical man, she allowed this condition of things to continue for some weeks, hoping that the menses would daily return, or at worst be only deferred to her next period, and that with their reappearance she would regain her health. The monthly period came round, and "though she felt bodily very ill, there was no show," the "bodily very ill" being nothing more than the symptom of suppressed or missed menstruation. She had already begun to suffer pain in the head and eyes, and a sense of fulness in both situations, neuralgia of the face, chest, and limbs, pain and weakness in the back and loins, weariness and lassitude, petulancy of temper, peevishness and fretfulness which she could not command. At the time of the next monthly period, there was no appearance of the catamenia, and the only difference that obtained in the symptoms, was an increase of their intensity. She missed four periods. After the fourth had passed without a return to her natural health, she consulted me.

She was ordered a warm hip bath every second night, mustard poultices to the hypogastric region, and to the inside of the thighs ; the bowels were well opened by means of the sulphate of magnesia, the breasts were well rubbed three times daily by a nurse; she was made to take as much exercise as she could in the open air, but not so much as to fatigue her, and every kind of nutriment in quantities that the stomach would bear. Besides this, she was put upon the ethereal tincture of ergot, and galvanised every night or every other night. The manner in which I applied the galvanism was the following :—

The poles were placed on the abdomen as nearly as possible at points corresponding to the sides of the womb; by "sides" I mean the outer edges, and after the electricity had been conveyed for some minutes in a continuous current, the plan of its administration was altered, and it was given in shock currents. The position of the poles was changed, one was placed over the right and the other over the left ovary, the continuous and shock currents being both employed in the same manner that I have just described. I now had one pole put by the attendant upon one breast, as near the nipple as I could without being actually upon it, and the other upon the opposite ovary ; then the poles were placed, one on the right breast, and the other on the ovary of the same side, and the electricity used as before mentioned ; again, the poles were shifted, and one was put upon the left breast, while the other was pressed against the integument of the abdomen, immediately over the situation of the left ovary. This latter application of the galvanism could not be tolerated, because of the "cramping sensation in the heart," and because of the distress occasioned by it. The upper pole was, therefore, removed to the right breast, and the currents, both the continuous and the shock, were given in a cross manner ; that is, the right breast and the left ovary were the parts through which the electricity was conveyed into the system.

As the ergot did not seem to act in any other way than in griping her, and in making her feel intoxicated, it was laid aside, and the oil of savin substituted, in ten-drop doses, three times daily. Moreover, on the third morning, before the day she ought to become unwell, I gave her a draught containing fifteen minims of the oil ; on the morning following she had thirty minims, and on the day that she expected the catamenia to return, I had the satisfaction of hearing that a white discharge had made its appearance. This discharge I looked upon as vicarious.

The effect of the treatment was as desired. It occasioned pains in the ovaries and in the womb ; also in the latter it created a bearing-down sensation, as though the patient wanted to pass something and could not. The savin did not occasion sickness, as I had adopted the precaution of ordering it to be taken immediately after meals ; and the only discomfort she experienced from it was "the repeating of the taste of it in the mouth." The electricity had been discontinued for three or four days preceding the day on which the return of the menses was expected, and both it and the oil were left off when that day had passed, in order to allow a rest from all treatment, so that when it was again begun there might be more signal effect. Three weeks before the next period should make its appearance the oil and electricity were begun. The latter, as on the previous occasion, was laid aside a few days before the looked for resumption of the menstrual function, as the patient thought it had on former occasions driven away the pains natural to "the period," by being continued up to the very time. The menstrual nisus began to declare itself, as it had in the last month, by the commencement of the pains ; and she felt assured that at the set time of life the natural discharge would appear. The menses did come on at the exact period, to the relief not alone of the body, but of the mind, and her entire condition.

The second case which I shall here mention is that of Miss V., aged about 37.

For some time she had been in delicate health, and had been losing flesh. She is of spare habit, but states that not long ago she was plump and in good condition ; now, however, the face is pale, thin, and the features are drawn and pinched, the entire of the body is wasted, and its surface pale and unhealthy-looking. The bowels are generally constipated, and require medicine to move them.

In tracing the history of her present affection, I gained from her the information that about six months previously, whilst she was "unwell," she got a fright, and had also allowed her feet to get damp ; that the menstrual flow was by these two causes at once arrested, and had not since returned, and that she had gradually got thinner and thinner, had been teased with vagino-labial irritation, had lost her inclination for food and for society, and had fallen into the bad state of health in which I now found her.

The manifest first indication was to clear out the bowels, and this was effected by means of sulphate magnesia, in these cases an admirable aperient when combined with certain adjuvants. Afterwards treatment was adopted in her case similar to that pursued so successfully in the other. On the morning of the day upon which the menses were looked for, there was a bleeding of the nose, and in the

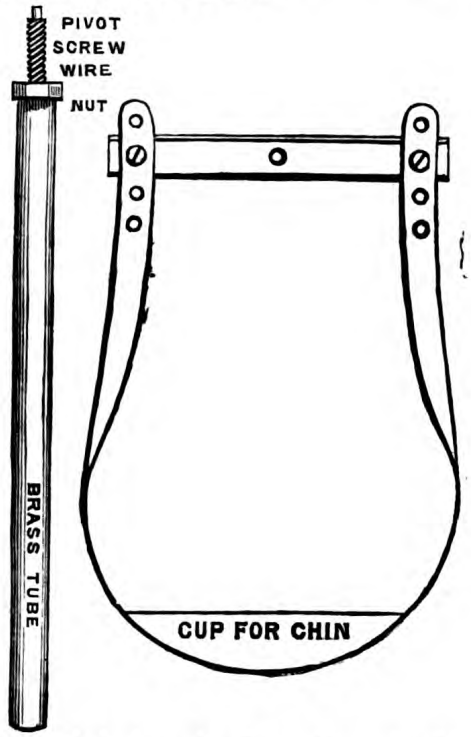
course of the day the catamenia made their appearance. The discharge, however, disappeared on the same day, but on the following morning the epistaxis returned, and with it the menstrual flow. Since then the patient did well and has been restored to health.

I could recite many other cases similar to these I have quoted, but for all practical purposes I consider two distinctly typical, though in some points diametric, instances sufficient. At this moment I have under my care, in the hospital a young woman of 18, who is in appearance more like a child of twelve, and in whom all womanly development seems to have been arrested ; and I purpose treating her by uterine stimulants, and by electricity, partly to procure the growth of the womb, which is now as small as in infant life.

TAYLOR'S APPARATUS FOR POTT'S DISEASE IN THE CERVICAL AND UPPER DORSAL REGION MOUNTED ON THE PLASTER OF PARIS JACKET.

By CHARLES P. PUTNAM, M.D., Boston.

IN the "Transactions" of the American Medical Association, Prof. Sayre has described and figured an appliance for suspending the head in connection with the plaster of Paris jacket. The jacket of course only serves as a pedestal on which to erect what Prof. Sayre calls a "jury mast," but it certainly makes a very good pedestal.



Taylor's method of treating Pott's disease (*Archives of Clinical Surgery*, June 15, 1877) in the upper part of the spine is not, as is well known, to suspend the head and so draw the vertebræ apart, but to apply counter pressures on the chin and on the prominent vertebræ in such a way as to throw the weight of that part of the body which is above the diseased portion on to the articulating surfaces, and thereby relieve the bodies of the vertebræ.

The following has been found to be a simple and effective means of accomplishing this end.

The plaster jacket is put on in the ordinary way except that a promontory is built up from it at the back quite on to the diseased portion of the spine, and in the process of construction a brass tube about a foot long and half an inch in diameter is imbedded in the back of the jacket and in the promontory. When the plaster has set a large screw wire nearly fitting the tube is slipped into it so far that the upper end of the wire is at about the height of the chin, and it is kept in this position or adjusted at will by a nut which is screwed down so as to rest on the end of the tube. The threads are filed off for about half an inch at the top of the wire to form a pivot for the chin piece or collar.

The collar may be of the simple efficient kind ordinarily in use with Taylor's apparatus, but one that is equally efficient, very easy to make and only a little less sightly is composed of a short straight strip of iron or steel for the back part and a long strip bent into a bow or letter U for the front and sides. The straight piece has a hole in the middle to receive the pivot and a screw hole and screw at each end to attach the U piece, the ends of which are twisted so as to bring them into the proper plane. Several holes are drilled through these ends, those on one side being so large that they allow the head of the screw to pass through, whereby the collar is easily put on or removed.

The front part is finished to receive the chin in the usual manner.

The only advantages that can be claimed for this collar are its cheapness and more easy adjustibility.

In practice this method of applying Taylor's apparatus has left nothing to be desired except that the plaster of Paris became in a few days rather brittle. It was perhaps of poor quality. The difficulty was, however, overcome by covering it with a layer of bandages wet in silicate of potash, which has made it perfectly firm.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Notes on a Case of Ovariotomy, terminating in Sudden Death.

Under the care of Mr. E. STAMER O'GRADY,

Surgeon to the Hospital and Member of the Surgical Court of Examiners of the Royal College of Surgeons in Ireland.

C. W. (No. 2,727), a tall, well-made, healthy-looking woman, came under observation on the 18th November, of the year just ended. She stated that she was seven years married, and the mother of four children—the last a seven months' one, which lived only eight days, was born in the middle of the March preceding her admission to hospital. Catamenia had continued regular all through, usually lasting from five to seven days, until five weeks back, when she passed her time, and has not had any change since. The patient, who was a woman of exceptional intelligence for her rank in life, believed her ailment began six months before the birth of her last child, after which event she remained of large size, and subsequently continuing to increase rapidly, placed herself under the care of the gentleman—a former pupil and "resident" of the hospital—to whose courtesy I am indebted for this very interesting case. The abdomen was enormously distended, conveying to the eye the idea of even greater bulk than really existed, the circumference being 53 inches ; the distance from the ensiform cartilage to pubes 28 inches, and from the umbilicus to the left and right groins 11 and 14 inches respectively. The above measurements were taken when in the recumbent position, the patient lying on the back with the abdominal mass laterally supported. The abdominal parietes, somewhat œdematous in their inferior portions, were extremely thin, and when not so sustained it fell over to either side ; or, when patient was in the erect posture became markedly pendulous in front. Fluctuation was manifest in all directions, with notable distinctness.

It seemed as if some firm portions could be somewhat vaguely felt far back to the left side, and somewhat more obscurely yet to the right. The surface, except over a limited space in the region of the left loin, was universally and in all positions dull. Only on one occasion could resonance be very indistinctly elicited in the right loin, as she lay on the left side and turned well over and forward. Results of vaginal examination were entirely negative. There was some rigidity of the radial pulse, and the cardiac

action was rather weak, otherwise the woman's condition seemed in every way satisfactory. The urine was normal in quantity, and free from albumen or deposits. There had been no sickness of stomach, and notwithstanding the large dimensions comparatively little dyspnœa. A woman of cheerful, well-regulated disposition, she bore up against her formidable trouble with remarkable courage and hopefulness, desiring as early an operation as possible.

The operation was proceeded with on the 22nd in a private room in a wing usually used for administrative purposes, and detached from, though communicating with, the hospital proper. The condition of the bowels had been previously attended to—a healthy motion was passed on the morning of the operation; immediately prior to its commencement, the patient was dressed in the customary flannel suit, and the catheter used by the nurse. The perforated caoutchouc sheet protected the clothing, &c., from risk of wet. The incisions (*a*) made in the middle line, midway between the umbilicus and pubes, speedily opened the peritoneum, exposing the cyst, and letting some ascitic fluid escape. An ordinary steel sound introduced through the cut and swept round over the face of the cyst demonstrated that no anterior adhesions existed within the limits of its reach. The large curved tapper was now introduced, my colleague, Dr. Duffey and Dr. S. Mason, keeping up uniform pressure as the fluid (*b*) flowed off by the conducting tube into the receiving-bucket under the table. A second large chamber required perforation, when the collapsing cyst, firmly secured to the canula by the side rakes, was drawn partially out, its progress being checked by some moderately strong anterior adhesions, which now came within reach. These were easily broken down by the hand, but the growth could not yet be extracted in consequence of the amount of solid-like structure contained in the deeper portions of it, which necessitated the elongation upwards of the incision by an extra four inches, to enable it to be delivered; as this was effected, the great omentum—extensively and intimately adherent to the posterior surface of the growth—came with it. These adhesions were separated with the fingers, the different lacerated and freely-bleeding pieces of the torn omentum being taken in charge and securely held by my colleagues, Mr. Ledwich and Dr. T. P. Mason, during the detachment of the tumour. The pedicle, a long and moderately slender one was secured by clamp; to the face of its stump the actual cautery was subsequently freely applied. The extensive sites of the omental adhesions were so badly lacerated and bleeding that this structure, which, besides, was not in a healthy state, could only be dealt with by tying it in packets with carbolised catgut, and cutting off the different damaged portions at various lengths, as indicated for each segment respectively. Some fluid blood and coagula were removed from the pelvis, a large-sized caoutchouc drainage tube introduced along the pedicle, and its free extremity fastened to the clamp. Such portions of the peritoneal membrane, both visceral and parietal, as came into view, were very vascular and injected (*c*). The wound was closed with eight points of carbolised catgut suture; this was passed through by double needles from the peritoneal surface, so as to bring strips of equal width of this membrane on either side into apposition. Additional support was given by broad straps of adhesive plaster, and pads of warmed French cotton, all being kept duly in place by the three-tailed flannel roller. Chloroform administered by Mr. Shaw acted admirably; prior to commencing its inhalation two ounces of brandy were taken. In the early morning a light breakfast of beef-tea and toast had been given. On patient being placed in the heated bed ready prepared in the same room forty drops of Battley, with two ounces of whisky, were thrown up the rectum. An hour later a good deal of pain being complained of, the opiate was repeated, and was promptly followed by sleep of two hours' duration. On awakening she was easy, and satisfactory reaction had taken place. Eight ounces of urine were drawn off. During the day a good deal of sleep was enjoyed. Nothing but a little iced milk was given by the mouth, the stomach kept quiet, and quite free from any tendency whatever to sickness. At 6.30 p.m. it was ascertained that the drainage tube was acting well, sanguinolent fluid escaping; the catheter again withdrew eight ounces of urine. Pulse was now 120, skin soft and moist, facial aspect good. After midnight the pulse reached its acme, 130, with a temperature of 104°. A draught containing 10 grains of quinine, 30 drops of Battley, and 20 drops of tincture of digitalis, was given and retaind. During the night the above draught was repeated; the woman slept well. On one occasion only the stomach was very slightly sick when gulping up a mouthful of wind, to which annoyance she was subject occasionally. Shortly before day-break the nurse, observing some tendency to weakness, gave a stimulo-nutritive enema, containing 2 ounces whisky, 10 grains quinine, with some beef-tea. Amendment after this was prompt and marked.

At morning visit on the 23rd Mrs. W. was found apparently in excellent trim: she spoke of what a source of relief the operation had been to her, and how she felt far, far better than she had any expectation she could be so soon. The facial expression was all that could be desired. The pulse, now 118, was of good character and volume; the same thermometer as before used registered 101·8° (*a*) An ounce of brandy, beaten up with half an egg, was given, prior to commencing to dress the wound. There was considerable but not excessive tympany, and some tenderness existed along the immediate neighbourhood of the wound. The dressings adjacent to the orifice of the drainage-tube were saturated with a somewhat reddish discharge with rather offensive odour. The soiled portions of the dressings were clipped away, and, with a syringe, the nozzle of which was inserted into the tube, some six or eight ounces of reddish fluid were gently sucked up, and then a weak solution (about ℥iss. ad. ℥viij.) of carbolic acid in tepid water injected in successive portions of two ounces, each being withdrawn before injecting the succeeding portion. It was intended to follow the fourth and last two ounces to remain; some of it, however, escaped by the tube, though not sucked out by the syringe; this and the last previously injected portion came back as clear as introduced. During the process there was no sensation of pain, or, in fact, special consciousness of what was being done; the woman was gay and cheerful, speaking of her coming rapid recovery. Strips of lint, which had been soaked in glycerine, were placed along the edges of the cut, and the dressings were being readjusted [during the process of dressing the large pads of cotton supporting the hollow of the belly in the diaphragmatic region had been retained undisturbed in place by the hands of an assistant], when, in the midst of a passing word of *plaisanterie* the patient was indulging in respecting an independent circumstance which had occurred during the dressing, she suddenly said she felt dizzy, and instantaneously became unconscious—absolutely, as if from a stroke—the face flushed deeply and sweated profusely. The temperature was not tried, but undoubtedly

(*a*) In several operations, especially gastrotomy in its various forms, a director, having attached to the handle a sharp hook of very small size, will be found a most manageable and efficient instrument, lessens much the necessity for changing instruments. It changes and materially facilitates matters when structures have to be divided in layers.

(*b*) This was brownish in colour and somewhat viscid; over 7½ gallons were measured, besides more than another gallon which had been spilled. The "sac" weighed 3 lbs 12½ oz., the anterior and lateral portions being very thin, whilst the posterior part was composed of cavities containing masses like bunches of grapes in bladders, each filled with the varying fluids usually met with under such conditions.

(*c*) A similar condition, and to an equal degree, was observed when operating on a former case, which, however, on that occasion, happily terminated in recovery.

(*a*) On each occasion the temperature was taken in the axilla.

for some minutes it was very high. Coincidently there was spasm of both upper extremities, equally well marked on either side, the thumbs being deeply flexed into the hands, the fingers grasped tightly over them, the hands flexed on the forearms, and these on the arms. No spasmodic affection occurred in the face, or was observed, and it is believed such did not happen in the lower extremities. Soon the face paled, pulse became weaker and weaker, the respiration shallow and at more and more distant intervals; the body heat rapidly ran down, and in less than half-an-hour death supervened. Immediately on the occurrence of the attack every effort was made in the promptest possible manner (*a*) to attempt resuscitation. The seizure came on during the visit, my three dressers and two experienced nurses being also at the moment actually engaged with me in the service of the patient. There was, therefore, no time lost in having a powerful stimulant enema thrown up, a large hot poultice placed over the belly, and mustard sinapism over the region of the heart, together with subcutaneous injections of ether. The application, on a bit of soft cotton, to the nostrils of seven drops of nitrate of amyl *seemed* (*?*) to cause some momentary improvement, but such did not follow a second trial of this agent. My colleague, Dr. Duffey, kindly came to my aid, when a few minims of liq. ammoniæ well diluted were injected into the right external jugular; no effect appeared to follow; the case was now, however, utterly prostrate.

Dr. Duffey, Physician to the Hospital and Pathologist to the Rotunda Hospital, kindly made the autopsy, from the written report of which, taken by one of my dressers, Mr. M. A. Donnelly, the following is mainly summarised.

The wound was found to be firmly united throughout its extent, requiring considerable force to tear asunder the adherent peritoneal surfaces, the membrane being throughout injected, vascular, and studded with beads of lymph. Spleen larger than usual, lobulated in a peculiar form, but of healthy appearance. A sub-peritoneal hæmorrhagic clot was found opposite the convex margin of the stomach, as well as a similar one on the transverse colon. There had been no hæmorrhage from the omentum where it had been tied and divided. Some reddish fluid was in the pelvis, but there were no clots, and it was evident there had been no hæmorrhage whatever since the wound was closed after the operation. The uterus was healthy, but the right ovary showed on section some small cysts in its structure; it was scarcely enlarged, and had passed for sound at the time of the operation. The stomach was distended with flatus, and deeply stained with bile; the liver somewhat small and congested, its surface so extremely delicate that the slightest touch of the finger impinged it. The heart had a considerable amount of fat deposited on its walls, which were otherwise healthy; all the chambers were healthy; aorta somewhat atheromatous. The lungs did not collapse much, and there was slight hypostatic congestion, as well as a little pleural and pericardial effusion. General and well marked venous congestion, the vena Azygos specially being excessively full and turgid. The pulmonary artery contained some, and the pulmonary veins a considerable quantity, of fluid black blood.

The general appearance of the brain was healthy, the anterior half seeming, perhaps, somewhat anæmic, whilst the inferior surface of the cerebellum was rather hyper-vascular. The sinuses were very full and turgid, the arterial system empty, and, so far as the most careful investigation could ascertain, perfectly free from clots. Sections of the brain mass showed nothing wrong. Nowhere in the body could proof of the supposition that death was due to embolism be found.

The surgeon seldom happens to be a witness at the moment when sudden seizures such as and similar to what occurred in this case take place, the circumstances attendant on which have been given in considerable detail, and the accuracy of which can, on the present occasion, be vouched for. Probably, among those who may read the case there will be diversity of opinion as to the cause of death. Indeed, it may be a question as to how far there was direct connection, if any, between the operation and the result. In Peaslee's excellent work embolism is mentioned in a passing way as one of the possible causes of death after ovariotomy, but examination of the literature of the subject and the personal experience of surgeons, tend to show how rare a termination is such as that which occurred in the present case. The very careful autopsy made by a skilled and experienced pathologist failed to find proof of the supposition that death was caused by embolism, and so far favours the view of its being consequent on some obscure form of secondary shock. Our knowledge of the sudden mode in which carbolic acid kills when taken in its concentrated form as a poison goes for nothing in such a case as the present—in face of the habitual performance by some of their ovariotomy operations under the carbolised spray, much larger quantities, in more concentrated form, of this agent being so applied to the peritoneal membrane than was the case in this instance. Moreover, the employment of carbolised and other injections into the peritoneal cavity has long been a thoroughly well established line of practice. Perhaps there may be such a thing as similar individual idiosyncracy to this drug as exists in some folks with regard to mercury, &c., the use of which, we know, acts in some persons at once as direct and specific poisons—notably to the various anæsthetics, and in isolated individuals to even certain ordinary articles of diet. Speaking of ovariotomy under the spray, Mr. Spencer Wells very recently (*a*) says—"That no great harm is done by peritoneal absorption of carbolic acid," evidence which, though not very positive, shows that within his vast experience obvious mischief cannot have been traced to the local use of this agent. How far the disturbance of the *equilibrium* of the nervous centres dependent on the abstraction of the amount of fluid sucked out by the syringe, or the subsequent introduction of the smaller quantities, may have stood in relation of cause and effect to the result, the writer cannot say, but, in connection with the subject, may allude to the experimental investigations which have been recently made on the effects of intra-peritoneal injections. The temperature of the fluid injected was about blood heat. The formation of the drainage tube was such that no violence could possibly have occurred in either the abstraction or injection of the fluids, which processes, moreover, were conducted with the utmost gentleness. The syringe was fully charged on each occassion with the fluid, and contained no air. In no way could cannalisation have occurred. In one other case (*b*) of the writer's the fatal seizure seems to have occurred with almost equal rapidity. The woman was doing well apparently, when the facial aspect was observed to suddenly change, and become of a deep, dusky hue, active delirium immediately supervening. In that case the phenomena directly attendant on the seizure were given on the authority of the faithful and vigilant nurse who had charge of the subject of this communication, also, and who having been habitually placed in special charge of the various cases of this kind operated on by my colleagues and myself has had an experience in the after-treatment of cases of gastrotomy for both ovarian and uterine disease unequalled by that of any other nurse in Ireland.

(*a*) Taught by prior experience of the special necessity of being prepared for emergencies in ovariotomy cases, all matters likely to become suddenly required in such event are habitually, at Mercer's, placed in the room ready to hand before the operation. One case has occurred to the writer where he had every reason to believe the prompt use of a free stimulating enema "tided over" the patient, who afterwards recovered.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At the last meeting of this Society Mr. William Sedgwick, M.R.C.S., read a paper on "Maternal Impressions." He said it was an established fact in reproductive development that women, as a rule, transmitted with far more sensibility than men. The normal influence of the mothers on the intellectual development of her offspring had been well and familiarly expressed in the term "mother-wit," and in abnormal development it was well known that women often served to a greater extent than men as conductors of an inheritance which they did not share. It was popularly believed that it was the emotional impressions of the mother, and not those of the father, which admit of being imparted to the fœtus, in the form of "mother's marks." It has, however, been thought that either parent was capable of imaginatively affecting the offspring at the period of conception, and traces of this belief have been lately found among some of the tribes in Central Africa. The author remarked that there was a difference, between cases in which a modification of fœtal structure had been slowly effected through the influences of the perceptive faculties, and those cases in which emotional impressions had been supposed to act upon the fœtus by causing what has been erroneously described as a sudden arrest of development. It was often difficult to distinguish between the alleged influence of maternal impressions and that of heredity, but still many cases occurred in which complete elimination of hereditary influence might be made. He said that when maternal impression had been said to react on the nervous system of the offspring the effect might with equal probability be referred to some modifications of structure produced through the medium of the blood. Dr. Robert J. Lee had lately stated that it was most natural to suppose that maternal impressions would be most frequently followed by unnatural conditions of the intellect of the child than by any abnormalities of growth; but Mr. Sedgwick thought that the limitation of the influence of a maternal impression to a corresponding organ or tissue in the fœtus as a consequence of some slight and inappreciable alteration in the blood of the mother being imparted to the local nutrition of her offspring, might physiologically be regarded as more probably than limitation effected by nerve influence. The influence of the impression at an early period of pregnancy could only be conveyed to the part through the medium of the blood, and it was consequently improbable that the first stage in the production of abnormal development should be a local arrest of fœtal nutrition. Toward the conclusion of the paper Mr. Sedgwick directed attention to the evidence in favour of the influence of maternal impressions, derived from observations on the lower animals, and, with reference to the episode of Jacob's rods, they were apparently employed not to originate, but simply to aid in the increased production of especially marked offspring. There had been many illustrations of the effect produced by variously-coloured objects on the breeding of sheep and other animals since patriarchal times. Dr. Alexander Harvey had collected and published some satisfactory evidence on the subject, as had also other observers; and a good illustration of this alleged influence on the breeding of sheep had been lately communicated by a much-respected clergyman in the West of England. In reviewing the evidence which had been adduced in favour of a belief in the influence of maternal impressions, Mr. Sedgwick admitted that there was indirect evidence that the influence of the mind over the body might, in the case of pregnant women be so far extended as sometimes to affect the fœtus, and there was nothing which could be regarded as physiologically inconsistent with the belief in its uncorrupted form. But the direct evidence in its favour was limited to a comparatively small number of cases in which the maternal impressions, received at definite periods of pregnancy, had been fairly well authenticated before the birth of the offspring. Some of these cases had been clearly independent of hereditary influence, and none of them could be accounted for by any theory of coincidence. As the only recognised medium of communication in such cases was the blood, it was probable that the influence of the impression was always gradual, and never sudden, in its operation.—Mr. Savory said that there were some cases which could only be explained on the doctrine of maternal impression. There was not much difficulty in explaining the influence of physical interchanges between mother and offspring; the transmission of small-pox and of syphilis were instances of this. The influence of mind over physical conditions was shown in the changes produced in the milk of a suckling woman by emotion. But in the case of maternal impressions we have not only to imagine the effect of mental emotion in determining changes in structure, but the difficulty lay in understanding how a *mental* impression on the mother should, as it were, be translated into a corresponding physical impression on the fœtus.—Dr. Thin would like to have all reported cases of maternal impression submitted to the same scrutiny as Sir G. C. Lewis subjected instances of supposed centenarians. He was not aware that the subject of maternal impressions had ever been thoroughly investigated.—Dr. Matthews Duncan said that this question was one constantly being brought up at Societies, and the reason of its unsatisfactory nature was that writers failed to make the distinction between a coincidence and a consequence.—The President remarked that instead of writers allowing their imagination to play on assumed facts they should seek for positive facts on which to base their reasonings.

GENEVA INTERNATIONAL MEDICAL CONGRESS.

SECTION OF OPHTHALMOLOGY, OTOLOGY, AND LARYNGOSCOPY.

President. — M. Warlomont.

Translated by Archibald H. Jacob, M.D., F.R.C.S.,
Formerly Ophthalmic Surgeon and Aural Surgeon to the City o Dublin Hospital and Dublin Eye and Ear Infirmary.

M. Hattenhoff, of Geneva, read a memoir on

THE PROPHYLAXIS AND ETIOLOGY OF SHORT-SIGHTEDNESS,

of which the following are the conclusions:—1. The usual causes of myopia are over-work of the eye and heredity, of which the effects may be either distinct and separate or combined. 2. Hypermetropia, which is the normal condition of very many if not of the greatest number of healthy eyes when in a state of repose, may be transformed into axile myopia passing meanwhile through the stages of emmetropia and curvature myopia. 3. The progress of civilisation, and especially of book education, tend to increase the frequency of myopia. 4. The tendency to acquired myopia is often, but not always, hereditary: the influence of race on this predisposition is still an open question. 5. In work of the eye three principal causes act together in predisposed individuals tending to produce the anatomical lesions of progressive myopia; these are—*a*, accomodation; *b*, convergence of the visual axis; *c*, oculo-cephalic congestion. 6. The conditions of age, attitude, light, and duration, under which the eye labours; also the nature of the object on which vision is concentrated, and the state of the visual apparatus itself, all exercise a powerful influence on the development of myopia. 7. The prophylaxis of short sight consists in a system which will improve the hygienic condition of the individual, in and out of school, which can only be obtained by the joint efforts of the school physician and the sanitary authorities. The use of convex glasses by hypermetropic persons must also be included amongst preventive means.

In the discussion upon M. Hattenhoff's paper,

M. Galezowski remarked that, in consequence of the difficulty of diagnosing certain forms of distance myopia, it is probable that many children who are hypermetropic are really myopic. He acknowledges the frequency of hereditary myopia, but combated the idea that the more cultivated of the community are more usually myopic, citing in support of his opinion certain localities in France and Italy where short-sightedness is very frequent amongst the most ignorant classes. He also attached importance to the influence of race.

M. Landlot read a paper on

THE PERCEPTION OF FORM AND COLOUR.

He concluded from his investigations that the functions of the

eccentric parts of the retina are not equal under diminished light to those of the central portions, but that it is especially in the centre that perception of form (visual acuity) resides, while throughout the rest of the retina perception of colours is relatively more highly developed.

M. Dor read a paper on

DIATHESIC CATARACT,

in which he concluded, with certainty, from his observations, that a close relation exists, as pointed out by Dr. Tessier, between phosphatic urine and cataract. Phosphatic cataract, he said, is comparatively frequent, and ought henceforth to occupy a place in our nosological tables.

M. Warlomont read a communication on

THE INDICATIONS FOR ENUCLEATION OF THE EYE.

The following are his conclusions :—1. Sympathetic effects following upon injury of the eye are either primitive or secondary; the first of these present themselves a few days after the accident, the others at a longer or shorter period—months or years—after the wounded person has passed through the first effects of the injury. 2. When an eye has been altogether destroyed by the injury, and all hope of either retaining or recovering useful vision is lost it is of great service to the patient to relieve him of the injured organ by an enucleation under anæsthesia ; he is thus spared the immediate results of the wound—ophthalmia, &c.—and he may return within a day or two to his business, in an excellent state to receive an artificial eye, the wearing of which will be harmless ; at the same time he is preserved at once from all consecutive dangers ; if there be reason to believe that the wounded globe contains a foreign body the indication for its removal is still more urgent. 3. When an eye, lost by some cause, traumatic or not, or the stump which represents it, is the seat of continued or intermittent sensibility, or of an acute or chronic inflammatory condition, or contains a foreign body or a cretaceous cataract, enucleation is indicated as a prophylactic, even in the absence of every sympathetic manifestation. 4. The enucleation of a lost eye, though it may be totally painless, is still indicated if, as is quite possible, the second eye becomes the seat of symptoms attributable to sympathy.

M. Jacquemot made a communication on

INTRA-OCULAR SMOKE CLOUDS,

observed in certain cases of disease. In two syphilitic and one albuminuric cases the patients complained for several months on getting up in the morning of an appearance of thick smoke before their sight. Nothing was observable under the ophthalmoscope saving a slight pallor of the papilla, which did not exist in the evening.

Dr. Fiezal made a communication on

PREVENTIVE IRIDECTOMY IN GLAUCOMA.

From a long experience the author considers himself justified in proposing a preventive iridectomy upon the healthy eye at the same time as the operation is performed for cure of the diseased organ. He communicated nine cases in which the preventive iridectomy did not give origin to any subsequent trouble.

A discussion followed, from which the conclusion seemed to be entertained that Dr. Fiezal's operation is fully justified under certain circumstances.

M. Coppen contributed a paper upon

THE RELATIONS BETWEEN CERTAIN DISEASES OF THE EYE AND EAR,

and concluded with these words—"A reflex ophthalmia may arise from an injury of the twin eye. In the same way, it may arise from injury of any of the organs supplied by the trigominal nerve, *i.e.*, the teeth, the ears, &c. The anatomical lesions may be identical, and the effect of the sympathetic disease upon the affected eye as disastrous in the one as in the other case.

M. Colladon, of Geneva, read a communication upon

TENOTOMY OF THE TENSOR TYMPANI,

and gave expression to the following conclusions : —1. Tenotomy of the tensor tympani, which was proposed on theoretic grounds by Hyott, has only been subjected to experiment within the last ten years. It has been employed principally in cases of chronic catarrh of the middle ear with progressive deafness, disorders of the labyrinth, vertigo, humming in the ears, and all conditions depending more or less upon prior shortening or secondary contraction of the tensor tympani. 2. The operation is sufficiently easy, but the operator must possess enough dexterity to avoid injuring the promontory or the articulation of the malleus with the incus. 3. It is generally admitted that no permanent success can be attained by tenotomy ; the reason is that along with the shortening of the muscle there exists almost always in the middle ear pathological alterations upon which the division of it has no effect. In some cases the favourable result of the operation has appeared to continue in consequence of the paracentesis of the membrana tympani. 4. The effect of the operation may be serious, for cases have occurred of violent inflammation following upon it, and extending to the labyrinth, and accompanied by a marked increase of the deafness and the humming. 5. A more favourable result may probably be anticipated from a method of operation lately proposed by Professor Tröltsch. It consists in the partial division of the tendon at its insertion into the handle of the malleus in certain pathological conditions in which it has been shown that this insertion descends very low down.

In the discussion which followed the paper Professor Weber-Seil, of Berlin, protested against the conclusions of the author.

THE "MEDICAL PRESS" SPECIAL REPORT ON THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM.

Chapter VII.—Treatment : Curative, Preservative, and Preventive.

(Continued.)

Savory and Moore first prepared curara discs of the strength 1-200 of a grain, but noticing that the amount of soluble extract varied greatly, they were induced to increase the proportions. Subsequently, being requested to make discs containing 1-20th and 1-16th of a grain of curara, they employed the alkaloid, curarine, in order to ensure unformity, and produce definite physiological results. The curarine discs have one great merit, the almost absolute certainty as to dosage.

We need hardly mention that the syringe should be reserved for the use of curara alone, and that the surgeon must use every precaution, so as not to injure himself.

We shall lay down subsequently the conditions under which the curara should be used, so as to fairly test its value, for it would be unproductive of real advantage, to indiscriminately use it in every case of rabies. Unless it is employed by an operator, who understands its physiological action, the method of controlling its action, so as to know when to stop, it would be simply dooming the patient to a more speedy death, and virtually grafting on the original disease another poison. We have seen how this has been done under the old treatment, when the patient was bled almost to death, and then saturated with deadly poisons, which only masked the symptoms of rabies. Reserving, then, our conditions, we may proceed with the more general directions. Presuming that the diagnosis of rabies has been satisfactorily established, and that it is not confounded with any of those diseases we mentioned as sources of fallacy, attempts must be made to palliate the most urgent and distressing symptoms. As Fleming advises everything likely to excite the patient should be rigidly abstained from, and he should not be tormented by visitors, inquisitive spectators, or by anything likely to excite his paroxysms. We know that external influences induce more frequent and severe attacks of the patient's distressing symptoms, and common sense will, independent of medicine, at once suggest the necessity of guarding the patients against such excitants. Quietude is an absolute necessity, and all useless interference or attention should be avoided. There should be no allusion to the disease, and

no mention should be made as to the cause of it: thus dog's bites, &c., ought not to be spoken of, and the mind of the patient should be dispossessed, as far as possible, of the idea that he is suffering from rabies. As all the senses are generally morbid and painfully acute, everything likely to affect them should be abstained from; thus whispering in the room is to be condemned, and all manipulation tending to excite the exalted reflex irritability, as repeated attempts at drinking, is unwise; the patient's questions should only be replied to, and whatever he asks for, if believed to be proper for him, should be allowed. If the patient is an adult, precautions will be necessary against furious paroxysms; means for restraint must be at hand, and suitable attendants; but even when force has to be employed, it must be combined with gentleness. In the paroxysms and fits of fury there may be an irresistible desire to grasp something between the teeth, and this should be satisfied. It is easily done by placing a moistened napkin or handkerchief between the teeth; it may be removed as soon as the paroxysm is over. This will afford relief, whereas the neglect of it might increase the frenzy. In the more tranquil form of the disorder, or during the intervals between the paroxysms, whoever the patient has most confidence in, whether relative or acquaintance, should be allowed to be present. If necessary the patient may be conversed with, or read to, and anything done likely to draw his attention from his condition. This companion should never be the first to speak, and when the sufferer seeks to talk about his malady, other subjects for conversation should be adroitly introduced. If the patient is thoroughly convinced that his disease is rabies, and will persist in speaking of it, and especially if he believes his case is hopeless, it will be best not to oppose him, but to admit that such is the nature of the malady, and to hold out encouraging hopes by telling him of cases that have recovered. Every symptom should be described to him as a favourable omen in his progress towards recovery, and every means should be adopted to palliate the serious mental disturbance. We also know that owing to the hyperæsthetic condition, the patient is agitated by currents of air, the rustling of dresses, the shaking of the bed or of the floor, by light, sound, and other excitants of reflex actions and emotions, and these must also be carefully guarded against. For that purpose the patient should be placed in a room where all these conditions can be observed, and also seeing the evil effects of a bright light, the apartment should be darkened—the soothing influence of a modulated or darkened chamber in many diseases of a nervous nature is well known. As a rule, the medical treatment should be as little complicated as possible, and as it has lately been principally directed to soothing the nervous derangements, we can see by the tables the comparative effects of the various hypnotics, and their relative advantages. Chloroform has been used, but its effect as a pure curative has not been satisfactory; but it can be used as an auxiliary, for when under its influence injections of beef tea and other foods may be usefully made, thus the distress caused by swallowing will be avoided, and as little as possible given by the mouth. Chloral hydrate is also a valuable auxiliary, and seems to have had a powerful influence in alleviating the agonising sufferings, and may be advantageously employed either in the form of an enema or hypodermic injection.

For this purpose it has been used with advantage in the case that occurred at Doncaster, and also in the three cases that happened at Nottingham. Other soothing, narcotic, or sedative agents, as hyoscyamine, morphine, digitaline, and atropine, may be used either hypodermically or endermically. It must be remembered, however, that the tolerance for poisonous remedies is extreme, and in addition to their being given in larger doses, they should be also administered at short intervals. Attention to the bowels we need hardly allude to, for that will be almost affected by the enemas, but should constipation occur, a drop of croton oil will soon remedy it. Nitrite of amyl may be used as a sedative, and chlorate of potass to wash out the mouth, and saliva. This can be done with a sponge tied to a stick or brush.

Should the practitioner, have his attention directed to a case during the earlier symptoms, when the patient complains of a peculiar feeling of *malaise*, the Turkish bath may be advantageously resorted to. Without assigning a *modus operandi*, but on the general principles of the Turkish bath as a valuable auxiliary, not only for the restoration, but for the preservation of health, we can unhesitatingly, recommend it. We do not attach any importance to it as a curative agent *per se*, for though Dr. Buisson asserts, that he not only cured himself, but also eighty patients who had been bitten by rabid animals, his evidence is not satisfactory, as we have shown that rabies will not necessarily develop after the bite of a rabid animal, and that it has not succeeded as a curative when tried by other observers. As an auxiliary we should use it, in order to assist nature, to soothe the nervous system, to equalise the balance of the organs of the body, to cleanse the skin and thereby relieve the respiratory organs and the kidneys, for we know the intimate connection, if not in relation, still in function, of the large tract of the skin. We thus place the patient in as favourable conditions as possible. When the malady has actually declared itself, or made some progress, we cannot speak with such certainty of the assistance to be derived from the Turkish bath, for independently of the difficulty of applying it, it is a matter of opinion whether it might not increase the excitement, dyspnœa, and cerebro-spinal congestion. This can only be tested by experience. Turkish baths are not always available, but we have supplementary agents in the shape of domestic contrivances, which, to a certain extent, supply its place as the vapour bath. Individual ingenuity will improvise a method of applying hot air, if considered necessary, but it must be looked upon, as we have said, purely as experimental and supplementary treatment, and if adopted must not interfere with the other conditions we have laid down, as far as regards quietude and needless manipulation. We need hardly impress the necessity of the attendants, protecting themselves against inoculation, with the saliva of the patient, for though this secretion may not be so virulent in man as in the dog, yet it is an indisputable fact, that it is potent enough to produce the malady. We have now laid down the outlines of a rational method of treatment, based on our present knowledge of this disease, and though we must confess, we are leaving Nature virtually to do her own work, still we are assisting her; this we have to do not only with rabies, but with the majority of diseases, whether typhoid fever, small-pox, insanity, pneumonia, or the various forms of affections of the kidney. Meddlesome interference, blind empiricism, reckless administration of strychnia, prussic acid, we may confidently assert, can never produce such satisfactory results, as following out the rules we have laid down on the broad line of common sense. Leaving, then, our general principles, we must formulate the special rules for an individual case or cases.

1. As rabies has become a national question, agitating the whole country from end to end, disturbing the very relations of life, exciting suspicion and distrust of our poor four-footed friend, the dog, we must insist on the necessity of Government appointing some special medical commissioners, who shall have charge of the treatment of every case of rabies reported. We have at present an organised staff, whose duty it is to inquire into the causation of zymotic affections, consisting of medical men specially fitted for scientific research, so that their sphere of action need only be extended. We know that mistakes in diagnosis have been made in the past, and, without the slightest reflection upon our professional brethren, mistakes will occur again. Virtually, the medical practitioner will thus have at his command the services of a consultant, and of an expert scientific observer, and we feel sure, in the interests of humanity, we shall meet with little objection on this point from our brethren. Necessarily, the services of this consulting officer cannot be instantaneously called into requi-

sition, but as we have the telegraph, and rapid methods of transit, as little time as possible would be lost, and as patients do not die, as in cholera, within a few hours, time will be alllowed for calling in aid. We shall thus, firstly, secure accuracy of diagnosis; and, secondly, the remedial action of curare will have a chance of being tested fairly and scientifically under the conditions we desiderate. We have said this poison was most deadly, and owing to its peculiar action its use should necessarily be restricted. It requires careful administration; it must be apparent that unless precautions are adopted its value cannot be fairly estimated, and therefore we require a crucial test. We shall, then insist on the following conditions:—

1st. Government shall appoint a sufficient number of qualified, scientific, medical men, if possible, at centres proportionate to population, and so situated geographically as to be readily accessible.

2nd. They shall be remunerated proportionately, and shall be at the service of any practitioner who telegraphs for them.

3rd. Until their arrival the medical officer in charge of the case shall follow out, not only our general directions, but also the following special observances:—

A. He shall at once secure the services of a special attendant, who has been accustomed to deal with cases of insanity, and who will not be alarmed should the patient have paroxysms of fury. Everyone acquainted with insanity is aware of the consternation excited in a household when any member of it is deprived of reason—how the patient is tied up with ropes in many cases, held forcibly down, and otherwise treated with brute force. But when brought to an asylum his bonds are cast away, and kindness and moral management take the place of brute force. For further particulars on this point we need only refer our readers to Conolly "On the Insane." Moral management and moral power are equally necessary in this disease—a disease so dreaded, and about which there is so much popular ignorance and superstition—and it is of the utmost importance that the nurse or attendant should be of the same intelligent type we have in many of our asylums. He will assist the medical officer in controlling the patient, if necessary, and in soothing or encouraging him.

B. If in an hospital so much the better, and so much easier of attainment, will it be to secure the second desideratum. The room should be carefully prepared. We see the advantage of this in special operations, as ovariotomy, and we are not asking too much to expect, if not similar, still precautions, which will have a tendency to assist nature in rescuing the patient from the jaws of death. The room then, should be capable of being warmed, without draughts or currents of air, and everything removed capable of exciting reflex action, or of irritating the unfortunate sufferer. Thus the floor should be rendered free from sound, the light should be subdued, all bright objects taken away, and the attendant move noiselessly; in other words, the intelligence of the medical officer will itself suggest all these more special precautions, which follow from our general principles.

C. The treatment must be of the simplest nature, and necessarily, the medical officer must be left a certain amount of intelligent discretion, attending to the action of the bowels, administering enemas of beef tea, or other aliment, controlling excitement, or the paroxysms of fury, if any; and here chloroform will prove of such advantage.

D. There are various ways of confining the patient to bed, as fastening a specially-made sheet over the bed, in such a manner that the patient will have the fullest power of moving and turning about. The hands are confined. This we have seen used with advantage in cases of fury and delirium from other causes. But these are points which each medical man will be able to solve himself, always remembering to *obtain the greatest amount of control with the least amount of expenditure of brute force.*

E. All visitors must be excluded, and as Fleming has pointed out, the patient may be allowed the choice of a friend or relative to sit with them.

F. If in an hospital, there will be some difficulty about the students, who, if introduced, must be so, not in large batches, but with the observance we have laid down, remembering the avoidance of the reproach of Martial: "Languebam sed tu comitus protinus ad me venisti Centum Symmache discipulis, centum me tetigere manus; Aquilone gelatæ: non habui $\frac{\text{Rabiem}}{\text{Febrem}}$ Symmache nunc habed."

Presuming that the consultant is summoned, and all these conditions observed, we have then the final appeal to curara. We have already explained its chemical action, nature, and dangers. The consultant will be specially acquainted with it, and he will apply it in the most scientific manner, and according to the experience he has of its physiological action. He will have, of course, to watch the case for some days, and considerable time and trouble will be involved in the task of experimentation. This is the least part of the difficulty. The self-devotion, self-sacrifice, zeal for the public good and public health, of our profession has been often tested and never found wanting. The records of our cholera, and other epidemics, have proved our disregard for self and life, while the Red Cross of Geneva at the present time bears witness to our professional spirit, not confined to one class or country, but to the whole of the human race. We could readily point at present, to a number of scientific observers, who have done painstaking, dangerous, laborious, but unremunerative work, and we do not anticipate the slightest difficulty in securing a similar class of men to undertake experiments so highly important to the human race. Should it not succeed, we must not still despair. Medicine has progressed, and guided by the past, and by the lessons taught us by our advances in pathology, in the treatment of many other diseases, both medical and surgical, we must have confidence in our profession, and look forward to the future. When Jupiter presented the woman formed by Vulcan with the mythological box, and a divine command never to raise its cover, amongst the fatal presents there was one which has ever been man's consolation.

Though Pandora, or as some say, Epimetheus, from curiosity, neglected the divine injunction, and opened the cover of the box, from which flew out over the world the host of miseries, calamities, diseases, and human woes that have since afflicted mankind, still Hope remained .... as hope remains for us.

Case CXXXII.—W. Murgatroyd, mill hand, male, æt. 17, bitten on the hand by a cat. The owner of the cat, as soon as he was informed of the accident, though he did not notice there was anything wrong with it, killed the cat, and gave as his reason that he would not keep a cat that would bite any one. There had been several mad dogs during the summer and autumn at Wilsden, but he did not know whether the cat had been bitten by any dog or animal.

Result and Time of Attack.—Nearly four months after. Fatal, second day.

Remarks.—Dr. Gustavus Le Lacheur deposed on oath:—I am a surgeon, at Wilsden. I first saw deceased on Sunday, January 16th, about 11 a.m., he was in bed in a very excited condition; his breathing very jerky; complained of slight pain and stiffness in left arm, and had considerable difficulty in swallowing. I gave him a sedative, and ordered cold applications to the spine, and ordered him to be watched during the night. His relatives informed me that he had been bitten by a cat in September, and that he had been very peculiar in his manner for the last two days. I next saw him about 10 a.m. on Monday, and found all the symptoms of hydrophobia. I had to have him strapped to the bed on account of his violence and of his attempts to bite those in attendance. At intervals he was perfectly sensible. He foamed at the mouth, and was unable to swallow. If liquids were offered he became convulsed. There is not the slightest doubt that the cause of death was hydrophobia.

Reference.—The above notes were obtained by the courtesy of the Coroner, William Barstow, Esq. Inquest held at Wilsden, Jan. 7, 1876.

Case CXXXIII.—Francis H., æt. 39, bitten on the hand by a dog. Wound cauterised with nitrate of silver; had healed up, but had broken out again about eight or nine days before he was taken ill.

Result and Time of Attack.—Two months after. Fatal.

Treatment.—Bromide of potassium, chloroform, &c. The head shaved, blister applied to back of head and nape of neck.

Post-mortem.—Heart rather contracted, normal in structure, old adhesions of pleura; right lung dark-red on section; crepitant everywhere except at margins, where there is a little emphysema. On pressure a dark-red frothy fluid exuded; left lung crepitant, dry, and emphysematous at margin; stomach congested in the greater part of its extent; brain weighed fifty ounces; vessels of the pia mater somewhat injected; a very little sub-arachnoid dropsy at posterior part; aspect of brain tissue and brain structure quite normal to the eye; spinal cord quite normal everywhere.

Reference.—*Lancet*, p. 82. 1877. Dr. Dunlop, Glasgow.

Case CXXXIV.—William Ray, æt. 56, bitten on the thumb and finger by a dog.

Result and Time of Attack.—Three months after. Fatal.

Treatment.—Atropine, morphia.

Remarks.—This case gave rise to some censure, as Dr. Martin, for the sake of experiment, took a basin containing water behind the door and allowed it to fall with a splash, which alarmed the man very much. He had read the report of the first case, and was very much alarmed by it, especially as his companions at work chaffed him about going mad. There was no *post-mortem*. Dr. Charteris seems to approve of Trousseau's maxim, to which we shall again allude. The first case was also severely animadverted on, as a dog was accidently admitted into the ward.

Reference.—*Lancet*, p. 123. 1877. Dr. Charteris, Glasgow.

Case CXXXV.—John M'G——, æt. 31, bitten on the hand by a dog; wound washed with carbolic acid. This patient was very much frightened of hydrophobia.

Result and Time of Attack.—A month after. Fatal.

Treatment.—Chloroform.

Remarks.—The report of the autopsy says every organ in the body was healthy. The brain and its membranes were slightly congested, which may have been the effect rather than the cause of the disease. We may safely say the Glasgow cases, either as records or for treatment, do not reflect much credit on the profession. They were the first cases, as far as known, that ever appeared in the city.

Reference.—*Lancet*, p. 161. 1877. Dr. Patterson, Glasgow.

Mr. Fleming (*Lancet*, Feb. 3rd, 1877) says, "I heartily endorse the remarks made by Mr. Richardson with regard to the treatment the unfortunate man suffering from hydrophobia received at the Glasgow Royal Infirmary. When I read the case in the *Lancet* I could scarcely believe it possible such torture could be inflicted, and without the slightest object to be gained, unless it were the satisfying of a most abnormal curiosity. The admission of a dog to the ward of a patient labouring under this much dreaded of all diseases, sprinkling water in his face, breathing upon and fanning him with a towel, blowing upon his neck and face, must surely be designated as nothing less than extreme cruelty, and certain to destroy the only chance of recovery the poor man may have had."

MEDICAL WITNESSES AT CORONERS' INQUESTS.

It transpired in the course of the recent Queen's Bench proceedings, that the coroner did not necessarily receive from the police, who informed him of a sudden death, any information as to what medical practitioner was in attendance before, at, or after the death, and consequently he was in a position to avoid calling in the medical attendant under the pretence that he did not know that any practitioner had seen the deceased about the time of death. The Council of the Irish Medical Association, resolving, if possible, to take away any excuse for an evasion of the law, preferred a request to the authorities of the Royal Irish Constabulary that instructions might be issued to the police that they shall in future always report to the coroner the name and address of the attending medical practitioner. The letter on behalf of the Association, was as follows:—

Irish Medical Association,
Royal College of Surgeons, Dublin,
December 12th, 1877.

Sir,—I am directed by the Council of the Irish Medical Association to forward to you the enclosed copy of the judgment delivered by the Court of Queen's Bench, on the 19th November, 1877, in the case of "Jacob *v.* Finlay," relative to Medical Witnesses at Coroners' Inquests; and to ask your attention to the 9th and 10th Vic., c. 37, s. 33, which directs the coroner to summon as medical witness at each inquest a "legally qualified medical practitioner, being at the time in actual practice at or near the place where such death happened," because this provision of the law is not generally complied with by the coroners, who, it appears, are not informed by the police—when giving notice of deaths for the purpose of inquests being held—of the name and address of any such practitioner, and in consequence they (the coroners) frequently call to their assistance some practitioner not qualified by being "*in actual practice at or near the place of death*," as directed by the Act above referred to. The Council are of opinion that the intention of the Legislature evidently was, that a medical practitioner who was likely to be aware of the facts connected with the occurrence of each sudden or violent death should be heard in evidence at the inquest, such practitioner being calculated to supply the most satisfactory evidence as to the cause of death; and have, therefore, directed me to bring the matter under your notice, in the hope that you may see fit to issue instructions to the police that they shall, when giving the usual notice to the coroners, inform them of the name and address of the legally qualified medical practitioner (if any) who was in attendance upon the deceased shortly before, at, or immediately after the occurrence of death—or of a legally qualified medical practitioner in actual practice at or near the place of death; in order that such medical practitioner may be summoned to give evidence at the inquest, in accordance with the provision of the law, whereby the Council believe the public interests would be served.

I have the honour to be, Sir,
Your obedient servant,
John H. Chapman,
Hon. Sec.

To the Inspector-General, Royal Irish Constabulary.

To this communication the following reply was received:—

Royal Irish Constabulary Office, Dublin Castle,
December 28, 1877.

Sir,—With reference to your letter of the 12th inst., I am directed by the Inspector-General to state, for the information of the Council of the Irish Medical Association, that, the matter in question having been since considered, instructions will be issued to the constabulary directing them when reporting a case of sudden death to the coroner to state also the name and address of the medical gentleman who was in attendance immediately before, or at, the time of death.

I am, Sir,
Your obedient servant,
R. Colomb,
Asst.-Inspector-General.

J. H. Chapman, Esq.,
60 Pembroke Road.

Our Irish readers will thus learn that it is the duty of the local police in all cases to furnish their name to the coroner. If, therefore, they should not be called as witnesses, they may assume that the coroner is responsible for the omission, and may take steps accordingly.

At the annual meeting of the Royal Ear Dispensary, Frith Street, Soho, last week, which was established in 1816, it was decided to rename the institution, which will be called in future the Royal Ear Hospital. At the same meeting, Dr. Lionel Beale, F.R.S. and Mr. John Wood, F.R.S., were elected consulting physician and surgeon respectively. Dr. Urban Pritchard's report for the year showed the finances and general progress of the hospital to be in a satisfactory condition.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 16, 1878.

PROSTITUTION: AND THE GENEVA CONGRESS.

PERHAPS some of the strongest indications of the moral and benevolent tendencies of the present age are to be found in the existence of the many societies and leagues that have been established for the purpose of suppressing some great social evil, or for the promotion of some great social good. Now it is a society for restricting the sale of intoxicating liquors, or the furtherance of total abstinence; now it is one for discouraging the excessive smoking of tobacco; to-day it is one for the prevention of cruelty to animals; to-morrow it will be something else. Among the more recent societies whose laudable object is to promote the physical and moral well-being of mankind, we may draw particular attention to the "British, Continental, and General Federation for the Abolition of Prostitution," especially as a legalised institution, and in connection with which an International Congress sat at Geneva only two or three months ago.

It may, however, be doubted whether either societies or federations, or acts of Parliament, can make a nation moral against its will. The immorality of a people, or of individuals, depends upon conditions quite beyond their control, and though it may be fostered by too much licence, it can never be stifled by artificial restraints. Even where a remarkable reformation takes place it is seldom lasting; the morality of one generation is succeeded by the licentiousness of the next; the Puritans by the "gay Cavaliers," an Oliver Cromwell by a Charles II. But if there be one task of this nature more difficult or more thankless than another, it is that which this International Federation has set itself to accomplish. It is true that the expression "for the abolition of prostitution" is somewhat qualified by the context, "especially regarded as an institution tolerated or legalised by Government." But it will presently appear sufficiently evident that the Federation has in view the abolition of prostitution *per se*, the "consideration of the causes which foster it, and the most effectual means of combating them."

It is not difficult to understand the insuperable obstacles this society will have to encounter in carrying out its scheme, and it may even be doubted whether this scheme is not of too Quixotic a nature to deserve very serious consideration. Prostitution has been a social evil at all times and in all countries, among the most civilised and most savage of mankind, with polygamous as well as with monogamous nations. The worshippers of Isis, the Babylonians and Ninevites, even the "chosen people" of God, did, as the youngest of our colonies do now, feel its malignant sting. No climate is uncongenial to this Upas tree of all human communities. If the burning sun of China, of India, and other Eastern nations has made its growth more gigantic and its fruit more loathsome, it is, on the other hand, dwarfed, but not killed, by the snows of Lapland and the icy plains of Siberia. Nor has anything ever been done, though oft attempted, to arrest this social canker. "The social history of mankind (says a distinguished writer), if it proves anything, proves this, that it is not by any means the nation with the severest code which is the most virtuous. No state, savage or civilised, could ever have more rigorous laws than those of Achin and Japan, and nowhere have the people been more flagitious. While the Draconic code was in force morals in Greece went to rot." In vain did the most virtuous of the Roman emperors endeavour to stem the torrent of vice around them. In vain were the seducer and seduced alike exposed to the penalty of death. In vain was the procurer punished by being burnt or having boiling metal poured down his throat. Nay, the very man who authorised this savage and cruel law, himself became a slave to the evil which he had vainly tried to stamp out, and towards the close of his reign was as dissolute and luxurious as the rest. Not only, indeed, was prostitution not materially controlled by legal or other forms of restraint, but there were not wanting many wise men who owned it to be an evil almost inseparable from all communities of men. Cato the Censor recognised prostitution, Solon did the same, and Cicero declared no State ever existed without it.

Let us now examine the machinery by the aid of which the International Federation of Morality hopes to abate an evil which so many before them have failed to check. The Federation is a "voluntary association of persons of both sexes, united with the common object of furthering the reform of public morality which the present condition of social life demands." It entrusts to its members the responsibility of forming themselves into sub-associations, and of instituting committees of action. These committees it encourages to enter into mutual friendly relations with its own central organisation, viz., the Executive Committee and its Secretaries, at the four offices at London, Liverpool, Neuchâtel, and Rome respectively. The federation avails itself of every legal means for the vindication of natural rights, the suppression of the irresponsible *Police des Mœurs*, and the aboli-

tion of all institutions which tend to give any kind of official sanction to vice. Recently—from the 17th to the 22nd of September, 1877—its leaders summoned an International Congress at Geneva, with the view of giving as much attention as possible to the question of prostitution, and to inquire into its outward manifestations and the remote causes which foster it, and the most effective means of combating them. The Congress distributed its labours into the five sections of Hygiene—Morality—Social Economy—Preventive and Reformatory Work—and Legislation. The debates in these sections have led to the series of resolutions which we shall have hereafter to consider. Moreover, the speeches, memoirs, letters, and documents which furnished the material of the discussion will appear in consecutive volumes, under the title of "Actes du Congrès," of the chief portion of which an English translation will be published. The above first international assemblage of the Federation consisted of 510 effective members, belonging to fifteen different nationalities. The general administration of the Congress was supported by a committee of honour, composed of 152 members of different nations, a committee of reception in the town of Geneva, a financial committee, and a bureau for translations.

Altogether this International Federation has an imposing appearance, but how far it will be able to carry out the programme which it proposes, whether the success of the undertaking is likely to be at all commensurate with the magnitude of its organisation, and whether the resolutions that have been adopted by the Geneva Congress are unexceptionable, both in theory and in practice, we shall take another opportunity of discussing.

M. RASPAIL, AND THE THERAPEUTICS OF CAMPHOR.

THE death of this venerable, eminent, and eccentric Frenchman has recently been a current topic of conversation not only in his own country where he had been so well known for half a century, but wherever socialism distracts, or science engages, the attention of mankind. There is more than one reason why the Radical Deputy for Marseilles had some claim upon the notice of the medical profession. As a political leader, as a socialist, as a journalist, we can have little sympathy for him, but as a man who achieved distinction in more than one branch of science, and moreover, as a remarkable charlatan, and an author of some popular works of medicine, we cannot fail to be interested in some of the incidents of his extraordinary and chequered career.

His scientific studies date as far back as 1824. They took a wide range, and embraced the subjects of botany, physiology, chemistry, palæontology and medical jurisprudence. His researches in botany and chemistry added greatly to his reputation, and contributed much to the advancement of these sciences, especially organic chemistry. It is, however, to his career as a quack doctor, to his peculiar notions about the nature and treatment of disease, and more especially to his strong belief in the medicinal virtues of camphor, that we would for a few moments direct the reader's attention.

Raspail astonished the medical profession by the boldness with which he pretended to have discovered the cause of all diseases, and their universal panacea; and curiously enough the revelations of modern pathology have shown that his strange and simple generalisation was not without some basis of truth. His idea was that all disease was due to the invasion of the living body by hosts of minute parasites, and as camphor would kill them, camphor was therefore the universal remedy. The boldness with which he propagated his views, the simplicity and plausibility of his doctrine, the credulity of the public, and the successful sale of his popular manuals of domestic medicine, were the means of converting the restless socialist and the poor cultivator of orthodox science into the rich and successful charlatan. Raspail, however, was no ordinary quack, he was a scientist, and absurd as his notion was as to camphor being a panacea, for all the ills that flesh is heir to, he made many valuable observations respecting the action and uses of this drug, which subsequent writers have confirmed, and he at all events was the means of drawing the attention of the profession in his country to a medicine which had been too much neglected, and which certainly possessed properties which entitled it to a high place in our list of therapeutic agents.

At the period to which we are now alluding, half the Parisian world was smoking Raspail's camphoretted cigarettes, while his pills, plasters, and ointments were also in general request. In a very different light are the virtues of this drug regarded by the profession at the present day, especially in this country. If we look into our works on materia medica, this would not appear to be the case, but, practically speaking, camphor is seldom prescribed in such doses as could ensure its physiological action on the system. Camphor mixture is about the only preparation that figures in the day-book of the general practitioner, and then merely as a vehicle for more potent medicines. That the therapeutic value of this drug should be so ignored, has often been to us a matter of surprise. Its virtues were duly recognised by the ancients, and it was often a favourite remedy with some of those older physicians who practised in an age when much more attention was given to the treatment of disease than is given now. Its well known physiological action should alone claim for it the attention of the practical physician. In small doses it is a diffusible stimulant of no mean order; it increases the action of the heart, and accelerates the circulation, excites a feeling of warmth all over the system, and promotes diaphoresis. It also exhilarates the spirits, and by one writer it has been described as causing a sensation of lightness, "the patient feeling as if she could fly." This feeling of exultation is very marked in some cases, and in an article in the *Quarterly Review*, September, 1851, on the Burning of Widows, it is stated that "the messengers found the Brahmin plying her with camphor, so that he was wholly unable to overcome the exultation which she exhibited." In larger doses camphor allays pain and spasm, promotes sleep, acting indeed as a narcotic; while in doses of 20 or 30 grains such poisonous symptoms as giddiness, dimness of vision, delirium, uncontrollable laughter, and even convulsions or paralysis, testify to the powerful influence which this drug may have on the system. It is, however,

in virtue of its extraordinary sedative influence on the genito-urinary system, and especially the generative organs of the female sex—of its anaphrodisiac properties—that camphor is most useful as a therapeutic agent. "Camphor," says Dr. Physick, "was made for women, with whom it always agrees." "It seems," another writer remarks, "to correct the toxic influence which the reproductive system has on the brain of some women." Its anaphrodisiac properties are shown by its beneficial action in the treatment of priapism and nymphomania; and it is said to abate the sexual sting by acting on the cerebro-spinal nerves of the external organs of generation, and not on the testicle, or ovary. Nevertheless, according to the testimony of Raspail, habitual large doses do not prevent conception nor induce impotence. A French physician, Dumas, who practised in the beginning of this century, is said to have given as much as 100 grs. in the course of a day. Raspail gave from five to 10 grs. in a wine-glass of water, with or without a few drops of ether. Dr. Tilt, one of the physicians who, in this country, have duly appreciated the value of camphor, gives it in the same manner, or prescribes Sir J. Murray's fluid camphor. Nor are the peculiar physiological effects of this drug the only reason why the practitioner of the present day should use it more frequently than he is in the habit of doing, inasmuch as there are several diseases in the treatment of which it has been found most efficacious by physicians in whose testimony we may place the greatest confidence. Among those few English authors who have had most experience of the action and uses of camphor, we may mention Drs. Copland, Dewees, and Tilt. The first mentioned physician highly recommends it in typhus and typhoid fevers, some forms of insanity, asthma, puerperal convulsions, gout, and dissection wounds. Where febrile pestilential and exanthematic affection assumed an adynamic form, he prescribes it in large doses in combination with tonics, stimulants, and antiseptics. In asthma, he remarks, camphor is one of the most generally beneficial of any of the class of narcotics, or antispasmodics, and we have at the present time an asthmatic patient under our care, in whom the administration of camphor affords the most decided relief. It is, however, in certain affections of the genito-urinary organs, that the value of this drug is most marked. Dr. Tilt says it is a valuable remedy in the treatment of several affections incidental to the change of life. In dysmenorrhœa, Dr. Dewees regarded it as the most certain and uniform palliative. In nymphomania, it has a remarkably sedative influence upon the genital organs. In the treatment of this, and similar disorders, in which Alibert, Esquirol, Copland, and Tilt, speak in high terms of its therapeutic virtues, it may now be advantageously given in combination with bromide of potassium. In cancer of the uterus, Dewees found that liberal doses of camphor afforded relief when opium failed to do so; while in the treatment of ovarian and uterine irritation, chordee, and some forms of hysteria, it will be likewise found a very valuable remedy.

If, therefore, M. Raspail added to the eccentricities of his career that of being a respectable charlatan, it cannot be denied that he chose for his nostrum no ordinary or worthless drug; and at all events his panacea was free from the objection attached to most quack remedies, inasmuch as there was no secret as to its nature and composition. He popularised a drug which probably often did much good and little harm; and if his death reminds us of the absurdity of relying upon a single remedy for the treatment of all diseases, it may also remind us that there is perhaps more than one drug that has fallen into unmerited disrepute, and the more general employment of which might be attended with greater benefit to our patients than some may feel inclined to admit.

Notes on Current Topics.

A Dublin Coroner's "Inquiry."

As we have felt it incumbent on us to refer very frequently to the abuses of the inquest system, and inasmuch as the pre-existing arrangements in Dublin may, we trust, be supposed to be on their death-bed, we feel constrained to notice the proceedings which transpired at the recent inquest on the body of Mr. Hayes. That gentleman was, our readers may remember, found lying dead with his head and body immersed in a tank on the roof of his house, which tank contained only about 8 inches of water. The question actually before the jury was whether he had been simply drowned by accident, or whether he had been stricken down by apoplexy or aneurism or some such sudden attack, and had fallen into the position in which he was found, and the verdict on this question was fraught with great importance, inasmuch as Mr. Hayes was heavily insured against accident in one of the Insurance Companies, whose liability to pay depended altogether upon the decision as to whether the death was due to disease or to accident. With such a circumstance before him, it might have been hoped that the coroner would have taken care that the investigation should be searching and conclusive, and the verdict perfectly clear of bias; and our reference to the proceedings now is to protest, that this so-called inquiry was neither one nor the other, that it was a mere colourable compliance with the law, which insists upon an inquest, and that the verdict was a foregone conclusion. If the newspaper reports are to be trusted, the verdict would seem to have emanated from the coroner, and been simply registered by the jury, and, though we are well aware that in Coroners' Courts this system of finding verdicts under the mandate of the presiding judge is very usual, we think that, in this instance, it would have been as well if the jury had been supplied with the requisite evidence, and left to judge for themselves. For example, we read in the *Irish Times* that at the opening of the inquiry, one of the juror's desired to ask whether the water or mud in the tank showed any indication that the deceased had struggled to extricate himself, but this very sensible and pertinent inquiry was at once settled by an observation from the coroner, that "they could not get any important evidence from that," and it was followed up by the remark that "it was quite obvious that the death was a natural one." The coroner then proceeded to make a speech, in the course of which he said "no medical evidence could establish whether or not deceased was dead before he got into the tank. It was a matter of humanity and good feeling that where it was not abso-

lutely necessary a *post-mortem* examination should be dispensed with, and in this case, even if it were held, and it was found that the deceased had some affection of the heart, it would not establish that death had not been caused by drowning. He might as well tell the jury plainly that supposing the deceased was insured in an accidental insurance company, it was very important that this point should be decided. The company, of course, had a duty to themselves to see that the death was really caused by an accident, but if there was a moot point he felt sure they would decide in favour of the person who had the policy. If, therefore, the jury could, it would be of great importance for them to find a direct verdict as to whether the death was or was not caused by an accident."

It occurs to us that the coroner hardly appreciated his duty on this occasion. He was there for the distinct purpose of determining the cause of death of Mr. Hayes, with which issue neither tenderness of sentiment nor money considerations have anything to do or should be permitted to interfere. It is not for coroners or coroners' juries to decide the liabilities of an Insurance Company. It is their function to find out the cause of death, and for this latter purpose every essential evidence should be forthcoming, whether or not its production might be distasteful to others. Under what we may call the order of the coroner, the jury in this case did not demand a *post-mortem* examination, and a verdict was found without one. We do not hesitate to express a strong opinion, that, without such an examination, and the circumstances, being so peculiar, the verdict of accidental death which was handed in is not worth the paper it was written on. There was some evidence as to the state of Mr. Hayes's health at some indefinitely distant period, but even the evidence of Dr Croly, who saw deceased immediately after death, was not taken. The coroner, as a medical man, must have known that the cause of such sudden attacks as might cause a person to fall into the water, could not be even guessed at without a careful *post-mortem* examination, and that the conditions which produced such an attack might be impossible of detection, even if searched for by a competent medical man five minutes before death. Mr. Hayes may quite probably have been accidentally drowned, but there may, with nearly as great probability, have been an apoplectic seizure, or ruptured aneurism, or some other unknown cause for his falling into the water. An inquiry, therefore, pursued on the principle of putting before the jury all the evidence of accident, and withholding that which at once might prove the existence of disease as at least a contributory cause, is, we feel it necessary to say, a public scandal, and a verdict thus arrived at should not have an atom of weight. That such proceedings can be tolerated in "the second city in the empire," and *coram populo*, is pretty conclusive proof that the public cares very little which way coroners' verdicts go. We, being interested in the purity and efficiency of such medico-legal inquiries, cannot look upon the matter with as little concern, and we therefore feel ourselves compelled to speak as we have done.

A SLIGHT shock of earthqnake was felt in the neighbou rhood of Whitchurch, Shropshire, on Friday last.

The Medical Practitioner of the Future.

THE *Students' Journal* devotes its editorial column in the first issue of the year to an article headed as above, and the opinions there enunciated are, we think, worthy of much thought. "Under the present system of medical education (it says) it seems necessary to ask ourselves the question—Where is the general practitioner of the future? Take the case of a student who enters a hospital immediately on leaving school, and suppose for the nonce that he is desirous of obtaining the diplomas which will allow him to practise upon his fellow-creatures. How grimly that word 'practise' sounds; it means that he is to gain his experience by endeavouring to cure the ills that flesh is heir to. The question inevitably arises, is a man with only this theoretical knowledge competent to battle with the intricacies of disease? We pine in vain for that Utopia which, we are afraid, will never be reached by the General Council of Medical Education. Why should anyone be allowed, in virtue of his diploma, gained by book-knowledge and cramming, to practise vivisection upon his fellow-men?

"It is of little use to complain of the present condition of affairs, unless at the same time we suggest some means by which this condition may be ameliorated. This desirable consummation might, in our opinion, best be reached by a revision of the present system of medical education. The lecture system has, we believe, had its day. When text-books were few, and hand-books scarce, the lecturer was a necessity, but at the present time, when all that he can tell us may be found quite as well said, and in many cases better, in the pages of some one or other of our leading text-books, he is an anachronism."

The writer, therefore, proposes to reduce considerably the number of lectures, and increase proportionately the tutorial instruction, and says "no greater mistake has ever been made in respect of medical education than when apprenticeship was entirely abolished."

If by "tutorial instruction" and "apprenticeship" our contemporary means personal teaching by a competent surgeon or physician at the bedside, or in presence of and upon the patient, we warmly approve of his view; but if by "tutorial instruction" he means grind-cramming as now existing, and if by "apprenticeship" he means the money-getting sham of the past generation, then we are widely at variance with him.

The lecture system has undoubtedly been abused and overdone, but it is even still altogether preferable to the parrot-teaching of the crammer, while, as regards apprenticeship, it may be said that its value so greatly depends upon the willingness and capacity of the master that it can never again be accepted as proof of competency or experience in the pupil. The education of the future, if the feeling of the profession at large can influence it, will be essentially *practical*. What the student cannot see for himself he must, of course, acquire by lecture or by book; but whatever is within his reach, he must in future learn with his eyes and his fingers, not with his ears and his imagination. It will, we hope, be the teaching of the future that the student shall see, manipulate, and record actual phenomena in physics and disease, and shall supplement the practical knowledge thus gained by following up the subject into its theory and correlation. The yearning or a more practical system of learning is bearing daily fruit

in the establishment of physical laboratories, the extension of experimental methods of instruction, and the establishment of clinical examinations, as the most important part of the qualifying test.

Lord Cairns on Homœopathy.

On the occasion of his laying the foundation stone of the Hahnemann Convalescent Home, Bournemouth, the Lord Chancellor said, "he was rejoiced to find they were going to pay tribute to the memory of Dr. Hahnemann, whose reputation went on increasing year by year, and who, he believed, was one of the greatest benefactors of the human race. Dr. Hahnemann was persecuted, but he survived it, and he (Lord Cairns) believed both from the direct benefit which his system had produced, and in the indirect benefit which it had contributed to as a curative to other systems, he would be regarded as one of the greatest benefactor we have ever had."

We are at a loss to understand on what grounds the noble and learned Lord based his belief that Hahnemann was one of the greatest benefactors of the human race. It is now more than eighty years since the doctrine of homœopathy was published to the world, and we should like to know what this system has done, either for the advancement of medical science or for the physical well-being of mankind, to warrant the use of such extravagant encomiums as those to which Lord Cairns gave expression. During this period the rapidity with which both the science and art of medicine have progressed is unparalleled by that of any previous age; but out of the numerous and great discoveries that have been made with respect to the nature or diagnosis, or treatment of disease there is not a single one for which we are indebted to Hahnemann or his followers. The use of the stethoscope, the almost mathematical precision with which we can mass out and diagnose diseases of the chest, the pathological import of albuminuria, the phenomena of embolism and thrombosis, the discovery of chloroform and other anæsthetics, the efficacy of bromide of potassium, iodide of potassium, and several other remedies in the treatment of disease, these and many more discoveries that have done so much for the relief of suffering humanity have been due entirely to the genius and research of those who have devoted themselves to the study of rational medicine. Homœopathy has, unintentionally, shown how much more may be left to the unaided powers of Nature in the treatment of diseases than was formerly supposed, and it acted as a very wholesome corrective to the system of polypharmacy which formerly prevailed. This much homœopathy has done, and no more. To say that it was one of the most beneficent discoveries of the age is merely indulging in hyperbole and flattery that are only excusable by the circumstances under which these extravagant opinions were expressed.

Vivisection.

On Thursday a public meeting was held at the Infant Schoolroom, Shadwell, under the presidency of the Rev Brenchley Kingsford, M.A., the rector, "to make known the cruel and demoralising nature of vivisection, and to petition against its practice." The meeting was called by the International Association for the Total Suppression of Vivisection. The rev. chairman, in the course of a brief introductory address, said that the advocates for total abolition of vivisection maintained that no advantage accrued to surgical knowledge or science of any kind from the practice of the inhuman and barbarous custom of vivisection; therefore, they were anxious to get rid of it. Mr. H. Ribton Cooke moved the first resolution, which was to the effect that "every effort should be used to procure the total abolition of vivisection in this country." Mr. Savage moved, "That this meeting desires to record its gratitude to Mr. Jas. Maden Holt, for the important services he has already rendered by pressing this subject on the attention of the Legislature, and pledges itself to use all available means in support of the bill he has promised to introduce with the same object into the next session of Parliament." Of course both these resolutions were carried. We were in hopes that the fanatical zeal recently shown by the anti-vivisectionists was beginning to abate, but it would appear from the above that the religious fervour of those enthusiasts has been only slumbering for a while. If, however, they think they are going to force Parliament into fresh legislation on the subject they are very much mistaken. Justice and common sense are against them. To prevent, as far as possible, wilful cruelty to animals is one thing, to put a stop to a few experiments which are for the most part painless, is another. Even if they did succeed in getting their bill passed it would not follow that the cause of humanity would be a gainer thereby. Its only effect would be that of driving our experimental physiologist over to France or Germany, where they would have the liberty of vivisecting many more animals than they would ever have thought of doing in their own country; so that our animals at home would only be protected at the expense of those abroad. Parliament, however, will have more sense than to listen to those petty agitators who, when they find their bill is not supported, will, it is to be hoped, cease troubling society with their crotchets and prejudices, and no longer endeavour to get up an artificial "public opinion" on the subject.

The Progress of Intemperance.

The progress of intemperance would seem to be startling rapid and universal, if we are to believe all the temperance journals, leagues, and societies in different parts of the world, are constantly telling us. When from America we have a good substantial "Quarterly Journal of Inebriety" as the official organ of the American Association for the Cure of Inebriates, when similar associations and journals are to be found in England also, and on the Continent, and when we read some of the appalling disclosures and the trumpet-tongued statistics scattered through the pages of these journals, our first impression is that at least a large portion of the civilised world is fast falling into a slough of intemperance. Of the amount of drunkenness prevalent in this country we are being constantly reminded by publicists of every grade of opinion. With regard to Scotland there was a few days ago in a daily paper the significant announcement that the Dundee Police Commissioners had provided several double-springed wheelbarrows to convey drunk and incapable persons to the police station during the Christmas holidays. In America the evil has been for

a long time attracting the attention of the legislature; and in that country, as elsewhere, a large proportion of its pauperism, disease, and crime have their origin in this prolific source. In Sweden, remarks Dr. Huss, things have come to such a point that if some energetic means are not adopted, the Swedish nation is menaced with incalculable evil. One million and a-half of persons, or about half the population of that country, annually consume from 140 to 175 pints of brandy or other spirits each. In the opinion of Dr. Huss, the Swedes, as a nation, have deteriorated in stature and physical strength, new diseases have appeared, and old ones have increased in number and intensity. The chief new disease is "epidemic chronic gastritis." In Australia the Colonial Government has enacted laws for the purpose of controlling the habitual drunkard; and even in France much more strong liquor is drunk than used formerly to be the case. They actually have a temperance journal, *La Temperance*, the second number of which has just appeared. If we couple with the above facts another well known fact, that secret drinking is also very prevalent among the middle and higher classes of society, it would be only affectation to deny that something must be done to stem the progress of an evil which bids fair to demoralise half the rising generation around us.

The British Science Association—Meeting in Dublin, 1878.

At the meeting of the executive committee last week, the Secretary read a communication from the Senate of the University of Leyden, in which the invitation of the executive committee was acknowledged with a warm expression of thanks. The names of any members who may purpose going to Dublin will be transmitted in due course. From the Royal Academy of Science at Turin a similar letter was received, in which the gratitude of that learned body was expressed for the invitation, and an assurance of co-operation given. In a letter received from Dr. Steele, Registrar of the Royal Dublin Society, it was stated that the council of that body intended holding a *conversazione* on the evening of the 15th August, to which the members of the British Association will be invited. Mr. Norwood, J.P., hon. sec., reported that at a meeting of the General Council, held in London, the following gentlemen were announced as having accepted the offices of presidents of sections:—

Section A.—Mathematics and Physical Sciences, Rev. Professor Salmon.

Section B.—Chemical Science, Professor Maxwell Simpson.

Section C.—Geology, Mr. John Evans.

Section D.—Biology, Mr. D. Flower. Professor Huxley will be one of the Vice-Presidents and Chairman of a department in this section; the third chairman is not nominated.

Section E.—Geography, Sir Wyville Thompson.

Section F.—Economic Science and Statistics, Professor Ingram.

Section G.—Mechanical Science, Mr. Edward Easton.

It was moved by Lord Rosse, seconded by Lord O'Hagan, and resolved—"That the hon. secretary be directed to request the co operation of the Queen's University in Ireland, that the Senate should nominate a member to represent the University on the executive committee, and that a copy of this resolution be forwarded to his Grace the Duke of Leinster (Chancellor), and to Sir Dominic Corrigan, Bart., M.D., (Vice-Chancellor of the Queen's University in Ireland)." The hon. treasurer announced that the total amount of subscriptions received to date was very nearly £1,800.

The Provident Dispensary Sham.

A contemporary prints an extract from the *Dorset County Chronicle* in which the opening of a shilling dispensary by the local general practitioner is heralded with a flourish of twelve-penny trumpets. "Mr. ——," we are informed, "has opened an institution of this *useful and commendable character* at his residence. 'By paying 1s. when patients attend the first time in each week, advice will be given, and one, two, or three bottles of medicine, as the case may require, provided the three visits are within the seven consecutive days.' The fourth rule informs us that 'all pills will be coated, in order to render them perfectly tasteless.' The eighth rule states that 'maternity cases are attended for 7s. 6d.' The tenth rule says: 'The fee for removal of a tooth is 1s.; but, on payment of 2s. 6d., it will be extracted without pain by means of laughing-gas (nitrous oxide).'"

If the surgeon finds it pay to give three bottles of what it pleases him to call medicine and three periods of his valuable time into the bargain, and if he can't get patients without advertising his shop in the local paper, we suppose we should be too sanguine if we entertained a hope that respect for his profession would deter him from that line of trade. Let us not, however, be treated to the "useful and commendable." It is too much!

A New University Magazine.

Glasgow University has started a magazine, the first number of which is before us. Of course the new venture does not aim to represent the medical element of the University exclusively, in fact, the first number scarcely touches medicine or medical politics at all. It rather aims at being a *Saturday Review* upon a small scale, although it can scarcely be expected to afford the talent of that journal. On the whole, the first number is fairly readable, and we wish it every success. If Glasgow University can support a magazine, it will be the first institution that has yet done it for any length of time. Many such ventures have been started, with both energy and talent, but the originators have not received that moral and material support which is so essential to the success of a periodical; hence the steam has been taken out of the principal workers, and a mushroom existence the result. We hope this may not be the case with the present undertaking, twopence is not a high price to put upon a magazine, so that upon the score of cost its readers should be many, and the support accorded commensurately large. The publishers are Messrs. Stenhouse, of Glasgow, and Messrs. Baillière, Tindall, and Cox, of London.

Increase of Lunacy in Surrey.

Last week we reported the serious increase of lunacy in the county of Essex, and the measures contemplated for the accommodation of patients. This increase is becoming general throughout the country, and the gravest fears naturally arise in the mind of every thoughtful per-

son. The county of Surrey has now to build another asylum to meet the rapid increase. The lunatic asylum provided at Wandsworth, has recently been enlarged, and a sum of £10,000 expended on the building; there is also the asylum at Earlswood for idiots. All this, however, is not sufficient accommodation for pauper lunatics; and a farm at Coulsdon, near Croydon, consisting of 148 acres, has been purchased for £25,000, for the erection of an additional county lunatic asylum for Surrey, which is estimated to cost £70,000.

The Protection of Life while Drunk.

THOUGH the matter is not exactly within the cognisance of a medical journal, we think it well to call attention to a reform instituted by a medical coroner in the Colonies, and deserving of being followed out in our own country. About four years have elapsed since Dr. Youl, the Melbourne coroner succeeded in getting a bye-law passed to the effect that all vessels lying at the piers must have nettings under their gangways. Dr. Youl had been struck with the large number of inquests he held upon sailors who had been drowned at night through a false step while going on board their vessels in a state of intoxication. Since that time he finds that his inquests have been reduced thirty per cent., which may fairly be traced to the nettings. Sailors are often found asleep in them of a morning, suspended over the water.

THE *Glasgow Medical Journal*, which has been in existence as a quarterly for the last nine years, appears as a monthly with the new volume. In altering its style, the editor frankly admits that it has not received such support as would warrant its continuance in that capacity; the discontinuance of the *Medico-Chirurgical Review* was the death-note for his own journal and that of many other quarterlies; the day being past when authors or readers could wait three or six months for their papers. Fully appreciating this change, he starts afresh, with renewed hopes that the alteration will be appreciated and supported accordingly.

THE Friday evening meetings of the Royal Institution before Easter will be devoted to discourses by Prof. Huxley, F.R.S., on William Harvey; by Mr. Preece, on the Telephone; by Matthew Arnold, on Equality; by Dr. P. L. Sclater, on Zoological Distribution and some of its Difficulties; by Dr. Liebreich, on the Deterioration of Oil Paintings; by Prof. Goldwin Smith, on the Influence of Geographical Circumstances on Political Character; by Sir Joseph Hooker, on the Distribution of Plants in North America; and by Prof. Roscoe, Lord Rayleigh, Prof. Tyndall, Prof. Dewar, and Sir John Lubbock, on subjects not yet announced.

THE annual general meeting of the Dublin branch of the British Medical Association will be held on Wednesday, 30th January, at the hour of 4 o'clock, p.m., in the Hall of the King and Queen's College of Physicians, Kildare Street. The President of the branch, Dr. Hudson, will deliver an address; the officers and council for the ensuing year will be elected, and other necessary business transacted. By the kind permission of the President and Fellows, the annual dinner of the branch will be in the College hall, at 7 o'clock p.m., on the day of the meeting.

A SAD accident occurred on Friday night at the Woolwich railway station. Whilst a female lunatic patient was being conveyed to the Kent County Asylum she suddenly broke away from those who had charge of her and threw herself on to the line as a train approached. Seeing this, the night inspector, Mr. Craft, at once leaped after her, drew her clear of the metals, but could not extricate himself, thus sacrificing his own life for that of a lunatic.

THERE was a general rise in the rates of mortality throughout the United Kingdom last week. London rose to 28, Edinburgh and Glasgow to 29, Dublin to 32, and Liverpool to 33 per 1,000 of the population. While Brighton, which has been fluctuating for some time past between 16 and 20, gave a death ratio last week of 27 per 1,000. This increase was due mainly to the excessive variableness of the temperature, the number of deaths from pulmonary diseases being much higher than any preceding week for the last nine months.

A SAD occurrence took place on Saturday week, by which Dr. Lang, of Southport, lost his life. Deceased incautiously carried a light with him for the purpose of discovering an escape of gas in his house, when a violent explosion suddenly occurred, killing him on the spot, and shaking the house almost from its foundation. Great commiseration is expressed by the inhabitants for this untoward accident.

IT was resolved at the meeting of the Manchester city council last week, by 48 members to three, that application should be made to parliament, to sanction the scheme for supplying Manchester and the adjoining towns with water from Thirlmere Lake. The cost of the scheme will be between three and four millions sterling. We do not, for a moment believe, that Parliament will sanction such a scheme.

PREVIOUS to the opening of Parliament a system of ventilation is being carried out in the House of Commons, which it is expected will remove the objections so frequently made, as to the stuffiness and impurity of the atmosphere during prolonged sittings.

A LETTER has been received from the Treasury intimating that £20,000, the first instalment of the grant by the Government for the buildings of the University of Edinburgh, will be inserted in the estimates this year.

A NEST of otters was discovered at Aversham Weir on Thursday last; one of the brood was captured, the rest escaped. This discovery is a little remarkable, as otters in the wild state were considered extinct in England.

Correspondence.

THE CLINICAL SOCIETY AND THE USE OF CHLORAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The inconvenient effects which occasionally follow the incautious or long continued use of the Hydrate of Chloral, have induced the Clinical Society to appoint a Committee for the purpose of investigating certain points in the action of this important drug. The scope of the inquiry has been defined within the following limits "To investigate what deleterious effects follow the prolonged and continuous use of chloral in ordinary doses."

The Committee consists of Sir William Jenner, Bart., Dr. Andrew Clark, Dr. Buzzard, Dr. Duckworth, Dr. Barlow, Dr. Farquharson.

It is evident that a report upon such a subject will be valuable in proportion to the number and accuracy of the observations upon which it is based; and in entering upon its task, the Committee therefore invites the co-operation of the profession at large, and especially of those members of it who enjoy the opportunities afforded by family practice. Every accurately noted fact, even though it be isolated and of little evident utility, will be of service, and from the mass of evidence which may thus be placed at its disposal, the Committee hope that some generalisation of a useful kind may at least be attempted.

We are, dear Sir,

Yours faithfully,

WILLIAM JENNER, M.D., Chairman.
ROBERT FARQUHARSON, M.D., Hon. Sec.

Clinical Society of London, 53 Berners Street.
January, 1878.

*** Appended to this letter is a list of queries upon which the Committee desire information from the profession. As the letter came to hand while we were at press, we are unable to find space for the schedule of questions. This, however, will be sent by return of post, on application to the Hon. Sec. as above, the Committee being anxious to obtain the widest experience possible.—ED.

Obituary.

WILLIAM STOKES, M.D., F.R.S., D.C.L.

THE death of Dr. Stokes, Physician to the Queen in Ireland, Regius Professor of Physic in the University of Dublin, and sometime representative of the Crown in the General Medical Council, is one of the events of the year, the life of which is yet so young, and, whoever of those who now occupy the firmest position in the arena of Irish medicine, may fall before its close, the profession, science and the community cannot lose any of their members more noted for his learning, or more deservedly respected for his personal character.

It is, indeed, as the *Freeman's Journal*, from whom we derive much of our information, long since Ireland has lost so renowned a son, or Dublin so eminent a citizen. William Stokes was born in the city in 1801, and had consequently reached his 76th year. He died on Monday, the 7th inst., at his villa at Sutton, having been for some time past in failing health, and having latterly retired altogether from professional practice, his system having sustained a severe shock by a fall from an outside car at Bray some five summers ago, from the effects of which he never completely rallied. Dr. Stokes was fourth in descent from the Gabriel Stokes who was Deputy-Surveyor of Ireland. Gabriel's two sons, John and Gabriel, were Scholars and Fellows of Trinity College, as was also Gabriel's son, Whitley, the father of the doctor who was thus the son, grandson, and grandnephew of Fellows of College. His father, Whitley, was, along with nearly all the eminent Irishmen of his day, an earnest sympathiser in the wrongs of his country; he joined the United Irishmen, and after '98 was suspended from his Fellowship for a year by the Visitors on account of his political opinions. In 1830 he became Professor of Physic to the University, and retained the appointment till 1842, when he was succeeded by his more distinguished son, the subject of the present memoir. William Stokes was never at school and never entered college. He was educated chiefly by the remarkable Rev. John Walker, F.T.C., who, in the early part of the century resigned his fellowship, left the Church of England, and founded the sect which bears his name. In 1821, young Stokes was sent to study medicine in Edinburgh, where, along with Sir Dominic Corrigan, he took his diploma in 1825. While a student, he attracted the notice of Dr. Alison, the father of the historian, and formed the beginning of an intimate friendship to which he so touchingly alluded in his address to the British Medical Association at Leamington, in 1865. In 1828 he married, and commenced his professional career, we believe, in French Street. In a couple of years he moved into York Street, and after many years' residence there, he moved to Merrion Square. In 1828 he published his first work on "The Application of the Stethoscope to the Diagnosis and Treatment of Thoracic Disease," which obtained an immediate recognition by the faculty, and laid the foundation of his fame. He was appointed physician to the Meath Hospital, and there, in conjunction with his great friend, Dr. Graves, initiated a general medical reform, and commenced the system of the then famed and now universal clinical lectures. He rose rapidly into an immense and lucrative private practice, which he retained as long as his health permitted. In 1832 he saw the first case of Asiatic cholera which visited this country. In 1837 he published his authoritative and masterly work on "The Diagnosis and Treatment of Diseases of the Chest," which brought him no end of honours and honorary degrees at home and abroad, and which may be said to have marked an era in the history of the profession. Two years after the appearance of the book, Trinity College conferred on him *honoris causa* their degree of M.D., and in the same year (1839) he was elected a Fellow of the King and Queen's College of Physicians in Ireland. On three separate occasions he was elected President of the ancient Corporation, and Foley's speaking statue erected in its hall in 1876, is the splendid testimony of the profession generally as to the esteem and admiration in which they held Dr. Stokes. In 1845 he was chosen Regius Professor of Physic to the University, T.C.D., on the death of his father, and was a worthy successor in the chair which had been filled by Stearne, Howard, Molyneux, Helsham, the friend of Swift and Delany, and by other men of eminence. In 1843, Dr. Stokes, along with Marsh, Graves, and Cusack, strove to abate some of the oppressive measures of Sir James Graham's Medical Charities Bill. He was examined before a committee of the House of Commons on the question, and he succeeded in effecting some amendments in the Act. In 1848, along with some coadjutors, he took a still more emphatic part in endeavouring to defeat the Dispensary Act, which, by its five-shillings-a-day payment, inflicted such a degradation on the profession, and such a cruel wrong on the medical men throughout the country who had charge of the famine-fever districts. In 1849 Dr. Stokes was appointed President of the King and Queen's College of Physicians in Ireland, and her Majesty's Physician in Ordinary in Ireland; and in the same year he produced the greatest and most important of all his books—"The Diseases of the Heart and Aorta." Oxford gave him its honorary D.C.L. in 1865, and Cambridge its honorary LL.D. in 1874. In 1875 the German Emperor presented him with the envied Prussian order "Pour la Mérite," in company with such distinguished men as Longfellow, Bancroft, and Schwann. Edinburgh also sent him its honorary LL.D. On the formation of the General Medical Council Dr. Stokes was nominated by the Crown as its Irish representative member, and he continued to discharge the duties of the office until last May, when he resigned it in consequence of failing health.

The space at our disposal forbids us enlarging upon Dr. Stokes's character. Like all really great men in our profession, his intellect would not bear the trammels of mere money-getting doctoring. He was a great physician and permitted no pursuit to interfere with his study of his profession and his care of his patients; but he was something more—a man of ardent literary and scientific taste, an astute observer, and a zealous worker in many extra-professional pursuits. As an archæologist his work on the life-labours of Petrie placed him in the leading position, and

probably secured for him the presidency of the Royal Irish Academy, which he vacated but recently. His views of medico-political questions were wide and liberal, and he was an earnest advocate of every measure which tended to raise medicine in the scientific and social scale. He has followed in his honoured age his worthy companions, Graves, Marsh, and Cusack, and leaves behind him an example which posterity may well point to as worthy of the imitation of generations yet to come.

DR. MAHONY, OF RUSH.

WITH deep regret we announce the death of the above popular and deservedly esteemed gentleman. Dr. Mahony had been for thirteen years Medical Officer of Rush and Lusk Dispensary Districts, and for four years previously held a similar position in Carrigaholt, co. Clare.

Deceased pre-eminently distinguished himself in his university career; he was one of the ablest scholars of his day, being profoundly read and thoroughly informed on almost every subject. He was, therefore, in society most entertaining, if not instructive. As a kind and warm-hearted friend, especially to those for whom in early life he formed an attachment, Dr. Mahony was unequalled. His sympathies were ever with the wants and privations of the poor of his district, whom, in the last hours of his illness, he did not forget.

He is sincerely and universally regretted by all who knew him, but especially by those who profited by his unremitting care and professional attention to them in their hours of illness. The people of Rush reserved to themselves the sad privilege of bearing on their stalwart shoulders, whilst they shed plenteous tears, the coffin of deceased, and carried it for nearly two miles before they would consign it to the hearse in attendance. The funeral, which was large and respectably attended, took place last week, the interment being in Glasnevin Cemetery.

Liverpool Medical Institution.—The following office-bearers were elected at the annual meeting of the Liverpool Medical Institution held January 8th, 1878:—*President*—Dr. Waters. *Vice-Presidents*—Dr. Tyster, Dr. Wm. Carter, Mr. Manifold, and Dr. Oxley. *Treasurer*—Dr. Dickinson. *Hon. Sec.*—Dr. Caton. *Hon. Sec. of Ordinary Meetings*—Mr. Puzey. *Hon. Librarian*—Dr. W. Macfie Campbell. *Members of Council*—Dr. Alexander, Dr. Bailey, Dr. Braidwood, Dr. Finegan, Mr. McCheane, Dr. Samuels, Mr. E. A. Browne, Mr. Harrison, Dr. Mathew Hill, Dr. S. Lewis, Dr. Robertson, and Dr. Turnbull. *Microscopical Committee.—President*—Dr. Braidwood. *Hon. Sec.*—Dr. Ashby. Drs. Davidson, Glynn, S. Hicks, Lupton, Paul; Messrs. Hamilton, Newton, and Rushton Parker.

NOTICES TO CORRESPONDENTS.

DR. LOWE.—We should have been glad to publish the letter, but pressure upon our space has rendered it necessary to close the discussion. Notice has already been given to that effect.

DOVER.—Thanks for paper with report of case of hydrophobia.

MR. B., Stockport.—Paper to hand.

WE are indebted to numerous correspondents for papers and extracts in reference to our "Report on Rabies."

DR. OFFENBERG, Rhenish Prussia.—Your letter received, for which accept our thanks. The *Paris Medical* we have always regarded as, and found, one of the most accurate of French journals, the name of the editor, Dr. J. A. Fort, commanding our confidence and respect. In the interests of truth and science, and in order thoroughly to investigate the matter, we have forwarded your letter to Dr. Fort, as our quotation was taken from his journal, and we did not verify it consequently. We have particulars of your own case, which will in due course be brought before the notice of our readers. This *reputed* case of Polli has also been mentioned in the *Lancet*, *Medical Times and Gazette*, and well illustrates the difficulty of arriving at facts. If we hear from Dr. Fort that a mistake has been made we shall correct it. You will have no doubt read that Dr. Acland, of Oxford, is reported to have said that from information he had received from Germany, from Dr. Victor Carus, he was not satisfied that your case was one of hydrophobia.

CURARA.—You must be a licensed experimentalist. Your experiments render you liable to legal action; they are very interesting and important.

SEAT OF WAR.—Thanks for your communication; we hope to give a *résumé* of what has been done. See *Progrès Medical*, Jan. 5, 1878.

POOR-LAW MEDICAL OFFICER.—We regret the unfavourable reply received in reference to *post-mortem* examinations. When such a simple and just request has been refused you need not expect another memorial will meet with a better fate.

SYDENHAM SOCIETY.—You should write to the Secretary.

J. W. MARTIN (Portlaw), and DR. WINN (London).—Your letters are unavoidably held over.

DR. L.—Join the English Poor-law Medical Officers' Association: Secretary, J. Wickham Barnes, F.R.C.S., 3 Bolt Court, Fleet Street, London. Every Poor-law Medical Officer should support that Society if they are really anxious for the improvement of their position.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Pantaleoni, Rome. Dr. Azam, Bordeaux. Dr. Offenberg, Rhenish Prussia. Dr. Bourneville, Paris. Dr. Lombe Atthill, Dublin. Mr. Fleming, London. Dr. Unthank, Cincinnati. Dr Passanha, Madras. Dr. Fort, Paris. Dr. Stretch Dowse, Hornsey. Dr. O'Reilly, Bishop Stortford. Mr. Gorham, Tunbridge. Dr. Rawson, Lichfield. Dr. Crothers, Nice. Dr. De Gorrequer Griffiths, Pimlico. Dr. Stewart, Bath. Dr. Harbinson, Lancaster. Mr. Osman Vincent, London. Mr. Worth, Nottingham. Mr. Squire, London. Dr. Beach Johnston, Rotherhithe. Mr. Reid, London. Dr. Horace Swete. The Registrar-General. Mr. Sparrow, Caistor. Mr. Corsellis, Wandsworth. Surgeon-Major Quill, Dublin. Dr. Dolan, Halifax. Mr. Sewill, London. Mr. J. Wickham Barnes, London. Mr. Jesse, Henbury. Dr. Cory, Ramsgate. Dr. Kelly, Bermondsey. Dr. Leared, London. Dr. Birch, London Dr. Pindler, Harpurhey, Manchester. Dr. Redman, Lincoln, Dr. John Drysdale, London. Dr. Kelty, Walsall. Dr. O'Flanagan, Houghton-le-Spring, Durham. Dr. Fox, London. Dr. Jagielski, London. Dr. Garland, Carrickmacross. Mr. Holmes, Dublin. Dr. Davys, Swords. Mr. Auld, Edinburgh. Mr. Mercier, St. John's Hospital. Dr. Macfie, Liverpool. Mr. John Moss, London. Sir William Jenner, Bart., London. Dr. Farquharson, London. Professor Attfield, London, &c., &c.

VACANCIES.

Balrothery Union, Luck Dispensary.—Medical Officer. Salary, £125. Election, Jan. 19.

Chiswick.—Medical Officer of Health for the Parish. Salary, £80. Endorsed applications to the care of Mr. Finnis, Prospect House, Turnham Green.

City of London Hospital for Diseases of the Chest.—Assistant Physician. Honorary. Candidates must address the Treasurer by the 26th inst. (See Advt.)

Durham County Hospital.—House Surgeon. Salary, £100, with board and lodging. Applications to the Hon. Sec., the College, Durham.

Holborn Union.—Dispenser. Salary, 104 guineas. Candidates must have Apothecaries' Society diploma. Address the Clerk to the Guardians, Gray's Inn Road, W.C.

Limerick Union Workhouse.—Resident Medical Officer. Salary, £100, with allowances. Election, Jan. 30.

Mountmellick Union, Clonaslee Dispensary.—Medical Officer. Salary, £100. Election, Jan. 24.

St. John's Hospital for Diseases of the Skin.—Honorary Medical Officer. Election, Jan 21. Applications to the Secretary, Leicester Square, London, W. (See Advt)

Sunderland Infirmary.—Senior House Surgeon. Salary commencing at £80, with board and residence. Applications to the Secretary of the Medical Board.

APPOINTMENTS.

BECK, R. C., M.R.C.S.E., Medical Officer for the Leavening District of the Malton Union, Yorkshire.

DAVIES, H. W., M.R.C.S.E., Resident Medical Officer to the Memorial Hospital, Jarrow-on-Tyne.

HICK, H., L.R.C.P.Ed., M.R.C.S., Medical Officer and Public Vaccinator for the Wortley District of the Bramley Union, Yorks.

HORNER, A. C., L.R.C.P.L., M.R.C.S.E., Resident Obstetric Assistant to the Westminster Hospital.

MACNAMARA, J., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer, &c., for the Urlingford Dispensary District of the Urlingford Union, in the Counties of Kilkenny and Tipperary.

O'KELLY, R. A., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, &c., for the Clonbrock Dispensary District of the Mountbellew Union, and for the Ahascragh Dispensary District of the Ballinasloe Union.

ROBINSON, H. S., M.R.C.S.E., Medical Officer to the County Gaol, Norwich.

Births.

BRISBANE.—Jan. 3, at 31 Park Road, Regent's Park, N.W., the wife of J. Brisbane, M.D., of a daughter.

MACAN.—Jan. 5, at 29 Lower Baggot Street, Dublin, the wife of Arthur Vernon Macan, M.B., F.K.Q.C.P., of a son.

Deaths.

CLARKE.—On Jan. 9, at Lynton Devon, John Clarke, M.R.C.S., aged 80.

GODFREY.—On Jan. 3, at Herne Bay, Thomas Godfrey, F.R.C.S.E., aged 58.

GUNN.—On Jan. 5, at Forres, Robert Gunn, M.D., aged 35.

HOLT.—On Jan. 11, at Uckington, Cheltenham, J. Rose Holt, M.R.C.S., aged 85.

HOOPER.—On Jan. 3, Alfred Hooper, F.R.C.S.Ed., of Clapham Common, aged 44.

KERR.—On Jan. 3, at Northumberland Street, Edinburgh, David Kerr, M.D., aged 73.

LANG.—On Jan. 5, John Lang, M.D., of Southport, aged 49.

LIPSETT.—On Jan. 6, at Raglan Road, Dublin, Lewis Edward Lipsett, F.R.C.S.I.

STOKES.—On Jan. 7, at Carreg Braec, Howth, co. Dublin, William Stokes, M.D., F.R.S., D.C.L. Oxon., Regius Professor of Physic in the University of Dublin, aged 76.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,
Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 23.)

Case IX.—*Syphilitic Disease of Left Cerebral Hemisphere, more particularly of Third Frontal Convolution. Peculiar Amnæsic Aphasia. Slight Dementia. Hyaloid Arterial Change.*

This case is especially interesting for the reason that for a long while there were no objective signs of paralysis except in those muscles whose co-ordinate movements were necessary to articulation, and these only became manifest when the will was exercised to demand their definite harmonious association. Although there was some paralysis of the muscles of the tongue, the want of voluntary power over this member was slight when compared with the muscular movements engendered through the facial nerve, so that any attempt on his part to co-ordinate the labials to whistle or to blow were abortive in a great measure. He was what might be termed passively emotional; he never became actively excited, but would laugh and cry alternately. The speech was rather of the drawling, hesitating character than of the stuttering, jabbering kind which we shall notice in the following case. He worked about the ward, doing everything that he was told automatically, with perfect good humour and *apparent* freedom of will. It was only at such times when he *endeavoured* to think and to exercise reasoning power that his mind, through the faults of language, gave evidence of weakness, which was clearly due to some gross lesion, as we shall find in going through the case.

F. B., æt. 43, came under my care on the 21st July, 1876, and died on Feb. 3rd, 1877. His ordinary facial aspect gave no indication of his cerebral state, either physical or mental; the muscular development and general *physique* was excellent; he was never known to have had a fit; he often complained of great pain over the forehead, which was always worse at night, and attended with increase of temperature. He was slightly demented, and the faculty of language was faulty. The articulation was slow and hesitating, the vocal cords acted freely, but the mucous membrane covering them was nodular, and old cicatrices were visible on the posterior wall of the pharynx. These parts were remarkable for their want of reflex excitability and common sensation. He contracted syphilis at the age of thirty, but it does not appear to have given him much trouble. His general health was good until he was forty years of age, when he became nervous and depressed, and sometimes when he went out for a walk he was unable to find his way home. Upon one or two occasions he staggered and felt giddy, but this condition was rare. His wife states that one morning when he got out of bed he was unable to speak for some hours, and from this time his speech was more or less affected.

In September, 1876, he first felt the *right* arm become weak; said he felt ill, and that the *right* arm and leg ached very much, and from this time the loss of power gradually increased in the muscles of this half of the body. In the following January the *right* hemiplegia was complete, with confirmed aphasia. The loss of power was greater than the loss of sensibility; there was hyperæsthesia and intense hyperalgia of the arm. In a short time after this the *left* leg became paralysed, but the *left* upper extremity remained normal. The whole of the

head was covered with psoriasis. On the 1st of February the temperature was recorded for a week as follows :—

	Morning.		Evening.	
	Right.	Left.	Right.	Left.
Feb. 1.—	103	102·2	103·2	101·8.
„ 2.—	101·6	101·6	103	101·4.
„ 3.—	101·8	101·4	101	101.
„ 4.—	101·8	101·6	102·2	101·4.
„ 5.—	101·6	101·6	101·6	101.
„ 6.—	101·2	101·6	103·6	102·4.
„ 7.—	101·8	102	101·5	101·8.

Subsequent observations proved the rule—that the paralysed limb is invariably hotter than the non-paralysed, no matter what is the cerebral lesion which gives origin to it. His general bodily health was now fast failing. On the 19th February he became unconscious, and died comatose.

At the *post-mortem* examination the skull was free from disease. The brain weighed 52 ounces. The arteries at the base were not atheromatous, but pale, patulous, and hyaloid. There was chronic inflammation of the membranes over both hemispheres, but more particularly over the *left*. The dura mater was found to be firmly adherent to the substance of the third frontal convolution of the *left* side by reason of a growth connected with its inner surface of the size of a small hen's egg. It had destroyed the brain substance, not only of this convolution, but also of the island of Riel, and exercised considerable pressure upon the corpus striatum. There was considerable softening of surrounding brain tissue. On the right side there was a patch of hæmorrhagic softening in the centre of the corpus striatum, but both optic thalami were free from any gross change. The tumour itself was more or less intimately blended with the surrounding textures, and, upon section, was seen to be of a pinkish-grey colour, somewhat vascular, with a central focus of soft mucoid degeneration. At the circumference its structure was firm and elastic. Under the microscope it was seen to be made up of amorphous and granular masses, a proliferation of fibrous tissue, and a multiplication of small nucleated cells. The vessels external to and about the mass showed the existence of minute aneurismal dilatations (which have been described by MM. Charcot and Bouchard), with peri-arterial sclerosis. In some parts the lumen of the vessels was almost obliterated by detritus and cell proliferation ; in others the proper tunics appeared to be nearly replaced by connective tissue and nucleated cell growths ; whilst in other parts where true sacculations existed the coats were formed mainly of elongated cell growths, devoid of muscular or connective tissue elements. The nerve cells had undergone pigmentary atrophic degeneration, and minute hæmorrhages were numerous.

Hornsey Lane, N.

(*To be continued.*)

RESTORATION OF THE EYELID AFTER EXCISION FOR INTRACTABLE ULCERATION. (*a*)

By EDW. WOLFENDEN COLLINS, F.R.C.S.I.,
Surgeon to Jervis Street Hospital.

DURING last March, S. D., a man 48 years of age, presented himself at Jervis Street Hospital, and was admitted under my care, suffering from Jacob's ulcer engaging the right lower eyelid. He was asthmatic, and of somewhat intemperate habits. There was no history of syphilis. Seven years previously the ulcer had its origin in a small pimple on the outer part of the lid. After a time, the pimple ulcerated, leaving a small, indolent, slowly-spreading sore, with a red uneven surface, and an indurated raised margin. A thin crust covered its surface, which, when it fell off or was picked off, quickly reformed. For a long time the sore was painless ; but about two years ago pain was experienced, whenever the ulcerated surface became exposed, owing to the falling of the crust. Twelve months later, bleeding regularly occurred on these occasions. Notwithstanding varied treatment, the sore had gradually spread during seven years, till it had involved the whole of the lower lid outside the punctum, as far as the outer canthus, presenting a superficial surface an inch in its transverse and half an inch in its vertical measurement. Its appearance is faithfully depicted in this water-colour drawing by Mr. McKernon, one of the students attending the hospital. In depth it was evident, from its extreme fixity, that the growth had invaded the tarsal cartilage and palpebral conjunctiva. The process of ectropium had already commenced. The surrounding skin was natural in colour ; and there were no glandular enlargements. From these circumstances, I had no doubt of the rodent character of the ulcer ; and I found the man willing to submit to whatever operation might be advisable for its complete removal. To this end, as my choice was limited to caustics or the knife, I selected the latter as being more expeditious, more certain, and attended with less prolonged suffering. Besides, as the cartilage and palpebral conjunctiva were infiltrated, their removal by the knife involved less danger to such important neighbouring structures as the eye and lachrymal passages. Considering the great disfigurement which the complete removal of the lower lid, and the parts adjacent to it below and externally, would entail, as well as the lasting condition of epiphora consequent thereon, I was led to the conclusion that the restoration of the lid by autoplasty, immediately subsequent to the excision of the diseased mass, was not only desirable to prevent disfigurement, but necessary to prevent epiphora and undue exposure of the eye. The special plastic operation which would best answer the requirements of the case, was no easy matter to determine. In the end, Dieffenbach's method of sliding a cheek-flap into the gap left by the previous excision, appeared to me the simplest and best. When, however, I applied the straight lines of his primary triangular excision to the case in hand, I found that, if the base of the triangle sufficiently cleared the infiltrated margin of the ulcer, its apex would reach the mouth. I then tried curved instead of straight lines, and ascertained that, by making a heart-shaped instead of a triangular space, I could limit myself to the excision of the diseased structures only, without interfering with the details of the subsequent autoplasty. To satisfy myself fully, I tried the double operation upon a dead subject in the dissecting room. The curved edge of the flap fitted admirably to its fellow without undue tension, and an arterial twig was seen coursing from below along the subcutaneous surface of the centre of the flap, a matter of no little importance as regarded its vitality. The details of the operation, thus arranged, I carried into effect on March 8, while the man was under the influence of ether. The entire lower lid external to the punctum, with its cartilage and conjunctival covering, was removed. The numerous vessels which spouted were either twisted or ligatured with carbolised catgut. A thick flap was then dissected up from the cheek, slid over, and secured in its new bed, along its inner border and at its outer angle, with entomological pins, and twisted floss-silk sutures. It was supported and covered with a pad of salicylic cotton and a bandage. On the third day after the operation, an outbreak of erysipelas, in the ward occasioned me some anxiety. The man was instantly removed to another ward ; but in a few days erysipelas, spreading from the wound, set in and ran its course over the head and face, without doing any damage to the flap, sufficient exit for any matter existing along its outer border. The upper and inner angle of the flap subsequently alone gave trouble, requiring constant attention and support by adhesive plaster.

On the 18th day, healthy granulations, on the portion of the cheek from which the flap had been taken, having reached the surface, I commenced the process of skin-grafting upon it, with the object of stimulating the surface,

(*a*) Paper read before the Surgical Society of Ireland. The discussion will be found at page 66.

hastening the healing process, and forming a more stable and pliant cicatrix. This process I continued every third day. In a month's time, the man was able to leave the hospital, the parts being all perfectly healed. The transplanted flap at that time was puffy. It has since gradually toned down, and now, ten months after the operation, it is nearly level with the surrounding skin. Owing to the process of skin-grafting, hardly any cicatrix marks the site on the cheek from which the flap was taken. Its surface is not depressed. Indeed, no traces of the operation exist, save the lines bounding the outer and inner side of the flap. There has been no return of the disease. The reconstructed eyelid performs its functions well. There is no epiphora, nor is there irritation of the eye. The man is in attendance for examination.

An accident occurred, which resulted in the destruction of the excised portion, containing the ulcer, previous to any microscopical examination. I regret this, as I was anxious, in so well marked an instance, to test the correctness of J. C. Warren's (Boston, U.S. 1872) doctrine that a rodent ulcer is a small-celled epithelioma. I may remark, that Mr. Golding Bird has recently demonstrated the opposite, viz., its non-epitheliomatous character, in a series of cases illustrated by drawings and microscopical preparations at the Med. Microscop. Soc. of London (*Med. Press and Circ.*, Jan. 24, 1877, p. 68). The subject has a very practical bearing.

When considering the question whether other operative interference was desirable than the mere removal of the diseased structures, I found much difference of opinion existing among those whose advice I sought, and no less difference in special treatises on ophthalmic surgery. Some such works are altogether silent on the point, in others it is discussed in the briefest manner. Mackenzie, however, fully discusses the subject, and gives an opinion totally adverse to autoplasty after excision, especially as regards the lower eyelid. He says, "so far as the loss of the lower lid is concerned, such a procedure is unnecessary. The deformity and inconvenience arising from the want of the lower lid is trifling. The mere contraction of the cicatrix suffices to bring up the cheek to the level of the lower edge of the orbit. The skin unites to the conjunctiva, and at first sight it is not observed that the eyelid has been removed. The palpebral opening is a little smaller than natural, both from above downwards on account of the upper lid descending more than usual, and transversely from the external angle of the lids having assumed a rounded form. Autoplasty under such circumstances, would do little good. (*Treatise on the Eye*, 1830, p. 141). I think that this opinion should be received with some reservation. After so extensive an excision as was required in the case I have detailed, I cannot hold that the deformity and inconvenience which would have arisen from the want of the lower lid would have been trifling; or that a carefully planned plastic operation for its restoration was either unnecessary or likely to do little good. Other oculists not only justify, but recommend autoplasty after excision of the lower lid. Some have manifested a preference for the method of operation I adopted, the principles of which were originally suggested by Prof. Dieffenbach of Berlin, (Caspar's *Wochenshrift*, 1835, No. 1, p. 8: abstracted in "A report upon the Progress of Plastic Surgery" in the *Brit. and For. Medical Review*, April 1839, vol vii., p. 405). I have ascertained that in 1835, Prof. Ammon, of Dresden, successfully performed this operation for cancer, engaging two-thirds of the lower, and a small portion of the upper lid (Ammon's *Zeitschrift fur Ophthalmologie*, 1835, vol. iv., p. 428); and he states that the same operation has proved successful in the hands of Profs. Fricke, of Hamburg, and Ekström of Stockholm. For the cure of severe ectropium, the operation is so thoroughly recognised as to need no comment. For the restoration of the eyelid after excision for intractable ulceration, it is not so recognised a procedure. Among surgeons of our own day, Bader recommends autoplasty in such cases, leaving the method of operation to be determined by the surgeon, as may suit his individual case (Cooper's *Surg. Dict.*, last ed., vol. ii. Art "Tumours of Eyelids"). Such is also the advice of M. Nélaton. "When the ulceration includes the entire thickness of the lid," he remarks, "you should not hesitate to remove it in its entirety, and to subsequently resort to some form of blepharoplasty." (*Pathologie Chirurgicale*, 2nd ed. 1876, vol. iv., p. 157). I feel satisfied that this advice is judicious, that it indicates the most correct surgical procedure, and, if followed, will be agreeable from an æsthetic point of view, both to the operator and patient.

As regards the transplanted flap, the success of the operation, it appears to me, will depend, first, upon its thickness, so that it may include the subcutaneous connective tissue with the vessels before they become capillary; secondly, upon the large size and proper position of its pedicle, so that, while furnishing a copious vascular supply, even to the extremities of the flap, it may admit of gliding rather than torsion, and thus offer the least obstacle to the circulation through it; lastly, upon its form, so that it may be in its new bed without undue tension upon its points of attachment. The occurrence of erysipelas invading the flap, when fashioned with these precautions, need not be a cause for much anxiety.

I have indicated how far I departed from the method of Dieffenbach in the choice of curved instead of straight lines in the primary excision of the lid, and in the subsequent adoption of the expedient of skin-grafting to cover the surface denuded by the transplanted flap. It may be of some practical interest to use this case, to illustrate the advantages of such modifications, and their successful application, in cases of epithelial or other ulcerative processes destroying the whole thickness of the lid.

Clinical Records.

SAMARITAN FREE HOSPITAL.

Cases of cysts in the pelvis tapped per rectum and per vaginam.—Removal of a vesical calculus from a girl aged nine.—Oxaluria with symptoms of calculus.

(Under the care of Dr. ROUTH.)

THE following two cases of cysts in the pelvis, are probably instances of ovarian tumours or cysts of the broad ligament arrested in a early stage by operative interference.

Charlotte W., æt. 23, machinist, was admitted into the Dorset House branch of the Samaritan Hospital on October 10th, 1877.

She was tall and thin, with the thorax much flattened and the mammæ ill-developed, but she had lived well and had no signs of phthisis. Eleven months before admission, the patient was taken ill with violent pains in the back. A week after the cessation of the catamenia, she applied to an Infirmary in the North, in the town where she was living, for relief, which was given to her in a purely medical form, since after examination no operation, scarification, leeching, or even the introduction of a pessary was thought advisable. She persisted in her work at the sewing-machine till a week or two before admission into the Samaritan Hospital, and continued subject to severe pains in the lumbar and sacral region throughout the first week after her period. This was unaccompanied by any feverishness, but her appetite became impaired.

On examination, the hymen was found persistent, the uterus small, anteflected, and somewhat low down in the vagina. The cervix was small and conical, and behind it was a distinctly fluctuating tumour tender to the touch. Examined by the rectum, this cyst felt larger, but its upper limits could not be defined. It produced no distension whatever of the abdomen.

On October 16th, Dr. Routh tapped the tumour *per rectum* with a pneumatic aspirator, removing nearly a pint of an opalescent fluid. It was viscid, sp. g. 1008, neutral reaction with a deposit, one-eighth of its bulk of albumen after boiling with nitric acid. It closely resembled the contents of the simpler forms of ovarian cyst, and did not contain a trace of blood or pus. After tapping, the temperature never rose above

99·8, and on the day she was discharged, Oct. 29th, no trace of the tumour could be detected by digital examination of the pelvis per rectum or per vaginam. She still complained of a slight pain in the back.

Hannah E., æt. 28, married, was admitted into the same hospital in November, 1877.

She had only had one child, born five years ago, and ever since her confinement had suffered from pains in the pelvis and abdomen; besides she had been twice laid up with "the inflammation of the womb." In the left iliac fossa was a fluctuating tumour, the size of a fœtal head, easily detected *per vaginam*, and not tender to the touch. She was subject to leucorrhœa, her catamenia were regular, though scanty; a week before admission she was taken with a feverish attack, accompanied by rigors.

On Nov. 30th, Dr. Routh tapped her *per vaginam* by means of an aspirator. About half a pint of serous fluid was withdrawn; the first drachm was quite clear, but the remainder stained with dark blood. The clear portion was highly albuminous. Her temperature the same evening rose to 100·2° in the axilla, 101·8° in the vagina, but on the third evening it fell to 99·8° in the vagina. The catamenia appeared on the fourth day, and she felt better and freer from pain than at any time since the commencement of her illness.

In both of the above cases, the cyst after tapping was injected with dilute tincture of iodine (two drachms to the quart of distilled water), a practice much in use at this hospital to prevent septic changes in open cavities. It has always been followed by the most satisfactory results.

It was found more convenient from the manner in which the most dependent portion of the cyst presented itself to the touch, to puncture *per vaginam* in the second case. But Dr. Routh generally prefers to puncture by the rectum, as he finds that such cysts are more accessible from that region. Moreover, the sphincter ani prevents the constant dribbling of offensive discharges from the cavity after puncture. On the other hand, fœtid discharges running continuously out of the vagina cause much distress to the patient. The tendency to tenesmus, produced by these irritating fluids, may be counteracted by frequent enemata containing disinfectants, and by the introduction of suppositories.

Under the care of Dr. DAY, and Mr. ALBAN DORAN.

Annie H., æt. 9, a pale, thin child, with an expression of constant suffering on her face, was brought by her mother in January, 1877, to the Metropolitan Dispensary, Fore Street, E.C. The child had been subject to incontinence of urine since her infancy, and for several weeks had suffered from severe dysuria. She complained of great pain towards the end of her school hours, during which period she was always forbidden to leave the room to make water. No calculus could be detected on sounding, and the patient's condition was much relieved by anti-strumous remedies. In July she became subject to more severe pain in the bladder, and distressing irritation about the vulva. She was therefore sent to the Samaritan Hospital, and admitted in October, under the care of Dr. Day. Great relief was afforded by rest in bed and belladonna, but micturition still caused great suffering. At the request of Dr. Day the child was examined under chloroform by Mr. Doran. The labia were found œdematous, the clitoris much enlarged. On passing a sound, a large calculus could be detected in the bladder. On October 23rd, the patient being put under chloroform, Mr. Doran widened the urethra, by means of a Simon's dilator, about a quarter of an inch in diameter at its orifice. After a little more dilatation of the urethra with the forefinger, the calculus was then readily extracted by a small pair of lithotomy forceps. It weighed two drachms and a half, and measured exactly one inch in its longer diameter. Its surface was rough, and it was composed of uric acid, with a coating of oxalate of lime.

On the evening after the operation, the patient's temperature rose to 100°. The next morning it was 98·8°, and all pain had disappeared. Until her discharge, ten days later, the little girl was troubled neither with dysuria nor incontinence of urine. Cod-liver oil and steel wine were ordered, and she was once more made an out-patient. When last seen by the operator at the Metropolitan Dispensary in the last week of the past November, she was in excellent health, with no signs of vesical irritation or incontinence of urine.

In this case Simon's dilator was used in preference to Weiss's instrument, as it is perfectly cylindrical, and hence less liable to seriously lacerate the urethra.

A week after this patient was discharged, a girl, aged ten, was admitted with almost precisely similar symptoms. The incontinence of urine, however, had existed only two years, the dysuria a few weeks. Her maternal uncle had been cut for stone when a youth. The child was carefully sounded, but no calculus could be detected. The urine deposited a considerable amount of mucus, which held in suspension a great number of crystals of oxalate of lime. After a few days' rest in bed, with doses of cod-liver oil and steel, all the bad symptoms disappeared. The patient is now free from any pain or inconvenience.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE Fourth Meeting of the Session was held on Friday January 4th, 1878.

Dr. ROBERT MCDONNELL, President of the College, in the Chair.

Dr. COLLINS read a paper on

RESTORATION OF THE EYELID AFTER EXCISION FOR INTRACTABLE ULCERATION.

which will be found on page 64.

Dr. BIGGER desired to make one or two observations on the paper just read by Dr. Collins, and he did so with all the less modesty, inasmuch as he had been associated with Professor von Dieffenbach during his great tour through Continental cities performing operations. His plan of operation in cases of the kind alluded to in the paper was very similar to that described by Dr. Collins. He always took the flap from the outside, and with as little twisting as possible he carried it as far as he could towards the nasal bone, because he wished to give support as far as possible, leaving the duct safe, and securing it by means of a vast number of small pins. He used to take a candle, and stick his pins in this candle to the number of some hundreds before he commenced the operation, and then he secured them as closely as possible together with little pieces of silk. He (Dr. Bigger) had seen some very good results even at that time from the operation, notwithstanding all the aids to surgery which were now so well known. He did not think that he saw any case in which there was not more or less occlusion or narrowing of the space between the lids. If Dr. Collins's case was free from any narrowing, it would be a remarkably successful operation, for he (the speaker) never saw that occur in almost any operation. During the last thirty years he had performed the operation seven or eight times on the lower lid. In the lower lid there was exceedingly little motion, the distance passed over was hardly a line in the opening and shutting of the lid, to draw it from its place. Of course the orbicular muscle did what it could, but there was very little of opposing muscle. These things being considered, they had very little to do but draw the parts carefully together, but still he thought there would always remain that feeling of narrowing across the eyelids.

Dr. HENRY KENNEDY said he had seen one case that was cured without any operation by caustics and internal tonics, in the shape chiefly of arsenic. As long as the case remained under his observation, it appeared to be a complete cure, but he was not aware if there was ever any return of the disease. Jacob called it the "ulcer that didn't heal." He (Dr. Kennedy) did not know if they were justified in going that far, for they knew that ulcers of an analogous character in other parts of the body had been cured. If he had the case that he had referred to, he would try hemlock in the very large doses in which they could now use that drug. It had cured skin cancer in every part of the body, and he thought that might be assumed to be the fact by the person who brought it forward. He meant, of course, with the local means in addition. It was very remarkable in the three or four cases that he had seen of the disease the difference in the sufferings. In one of them, there was extreme suffering, and in the others when the patients were spoken to in reference to the operation of caustics, they said they would bear with them, that it gave them very little annoyance, and they did not care for the

disfigurement. It was remarkable that in one case there was a great deal of suffering, while in the other four that he had seen there was almost none.

Mr. B. WILLS RICHARDSON said there was one author Mr. Collins had not alluded to in connection with the malignity of this ulcer, and that was Sir James Paget, who had examined ulcers of this description over and over again, and had specially alluded to the point that there were no cancerous elements infiltrated in either the wall or the bed of the true rodent ulcer.

Dr. BIGGER.—This ulcer was not what was commonly called Jacob's.

DR. COLLINS.—I looked upon it as a Jacob's ulcer—as a rodent ulcer.

The PRESIDENT wished merely to say that great confusion existed with regard to these ulcers. The name "rodent ulcer," and "Jacob's ulcer," and lupoid ulcerations and so on, and their confusion with epithelial affections was very great, as might be seen by anyone who looked into the literature of the subject at all. In the paper to which Mr. Collins had alluded, by Dr. Warren of Boston, which was one of the most exhaustive, and he thought one of the most thorough contributions that he knew of on the subject, the author had gone very carefully into the literature, and showed the immense diversity of opinion that prevailed. Mr. Richardson had spoken of Sir James Paget's view, which was very decided against its being epitheliomatous. He says that the elements, when examined microscopically, show no difference from those which abound in chronic ulceration. They had Mr. Jonathan Hutchinson holding the same opinion, while a very competent observer, Mr. Warren, differs from these two eminent authorities. All of those leading practitioners were thoroughly competent to form good opinions on the subject, and in his (the President's) opinion, such a difference could only arise from the fact that the ulcers that each examined had differed. He (the President) had examined a good many, and he was quite convinced that anyone who started in making himself a pathological observer, or thoroughly investigated the simpler forms first, would find around the edge of every chronic ulcer in the skin those well-known pearl-like appearances which so closely resembled epithelial tissue, and he would be led on a superficial examination to regard them as specimens of epitheliomatous structure; but a more thorough investigation showed that they were not the true and thorough epithelial growth. The name "Jacob's ulcer" was, he thought, an extremely unsatisfactory one. It was one of those terms which had been applied in rather a lax way to a great number of ulcerations around the eyelids. Efforts had been made to give something more definite of a name to it by calling it a rodent ulcer, distinguishing it between a *rodent* and an ulcer of an epithelial character. The question was whether there was not some fundamental difference between the genuine rodent ulcer and the true epithelial or epitheliomatous ulcer, which was of a cancerous nature, and having a tendency, though not a very rapid one, to contaminate the glands and spread to other parts eventually.

Dr. COLLINS, in reply, said he was obliged to those members of the Society who had spoken kindly of his paper, and might mention in reference to what Dr. Bigger had stated that he (Dr. Collins) had fully recognised Dr. von Dieffenbach's claim to the operation, and had mentioned his name in the course of his paper several times. With regard to the character of the ulcer, he called it a rodent ulcer, and he also called it Jacob's ulcer, as that name was applied to ulcers of various kinds about the head, and especially he thought the name was applied all through by Jacob to the non-epitheliomatous ulcer. He (Dr. Collins) was not able, unfortunately, to ascertain exactly microscopically the characteristics in his case of the ulcer, owing to the specimen having been destroyed. With regard to what Mr. Richardson had said about his not having recognised Sir James Paget as an authority on these matters, he (Dr. Collins) simply brought forward the two most recent communications on the subject of this ulcer, the communication by Mr. Warren, of Boston, who regarded it as epitheliomatous, and also the observations under the microscope and the preparations of Mr. Golding Bird, who took the very opposite view; and he (Dr. Collins) might say that he came to the same conclusion as Dr. McDonnell, the President, that where two such competent observers differed so widely, they must have been describing different microscopic preparations; in other words, some that were truly epitheliomatous, and others that were non-epitheliomatous. As regarded the tractability of the ulcer to cure, it had been going on and pursuing its course steadily for seven years, and he certainly regarded it as intractable to cure by the ordinary methods, such as hemlock; and as he stated in his paper, he thought there were only two methods of procedure, either to remove it by caustic or by the knife.

Mr. F. T. PORTER then read a paper

ON THE REMOVAL OF A FOREIGN BODY FROM THE LEFT LEG.

Of the many difficulties with which the surgeon has to contend, none task his ingenuity and patience more than the extraction of foreign bodies. The following case may not be devoid of interest. The patient, a little girl, aged 13, came under my notice on September 26th, 1877, and placed me in possession of the following history of her case. Towards the latter end of last June she was passing somewhat quickly upstairs, when a "crochet needle," which was in the pocket of her dress, entered the left leg at the lower end of the popliteal space, the handle of the needle at the same time breaking off. On the evening of the accident, she was admitted into a surgical hospital, where she remained for six weeks without benefit. The little girl left the hospital at the end of the sixth week, but in consequence of the needle remaining stationary she was unable to follow her avocation at the stationery business. Having ascertained the exact position of the foreign body by means of a suspended magnetised needle (prepared by Mr. Yeates), I cut down on it on October 13th, 1877. The operation, at which I was assisted by one of my pupils, consisted in an incision two inches long, and half an inch deep over the upper third of the tibialis anticus, the needle was found in the centre of the incision. The patient is now quite restored to health, and able to follow her business. I may add that the operation was painless, owing to the use of ether spray. A wish not to trespass on the time of the Society, prevents me enlarging on the case. In conclusion, I wish to elicit opinion as to the expediency in any case of cutting down on foreign bodies. I hold that it is no small advantage to relieve tension, even when we fail to find a foreign body. I also wish to elicit the experience of members of the Society on the value of the magnetised needle as a diagnostic agent in similar cases. The circumstance of a comparatively blunt needle forcing its way from back to front of leg, through so many dense structures, rather than passing downwards, is of interest.

The PRESIDENT remembered mentioning to the Society some time since, a case in which he had used the magnetised needle with very great success in discovering a needle the same as that removed and now exhibited by Mr. Porter. Those needles generally broke off close to the handle; and he remembered speaking at the time of the necessity there was of removing from the patient everything in the way of steel, such, for instance, as steel crinolines. There were many points of interest for the surgeon, in connexion with the subject of Mr. Porter's paper. It was a question in these cases how far it would not be better to *temporise*. When the needle made its way to the surface, it would make the operation a comparatively simple one. The result of the case now detailed seemed to have justified the course adopted.

Dr. BIGGER said that many of the members of the Society would remember a remarkable case in which no less than about three hundred needles were found in one person. The patient had been a nurse in the Whitworth Hospital, and was transferred to the Richmond Hospital, and she finally came to her death by a needle getting into the elbow-joint. Needles came from all parts of her body. How they got there remained a secret, but the supposition was that she had swallowed them. It was very curious indeed how needles got into various parts of the body without any knowledge of how they were introduced. There was nothing more common, and he had frequently seen them taken from the bodies of children. It was a question whether they should cut down upon them, for sometimes it was a matter of great difficulty. If they cut down upon the middle of the needle they could get neither one way or the other, and what were they to do then? In such a case—and he had met two or three—he thought the wisest thing was to cut the needle in two, and then he afterwards got both ends out

by simple traction. He was not quite sure whether that plan had been adopted by anyone else. Fish-hooks also frequently got into fingers, hands, and heads, and certainly to cut down on these things often puzzled a surgeon even accustomed to hard operations.

The PRESIDENT remarked that it had been proposed as a method of extracting needles under such circumstances, to get magnets sufficiently strong to draw them out. He did not remember who made that suggestion. He remembered mentioning to the Society a case in which he had used a magnetised needle for diagnosis, where a crochet needle had entered close to the knee-joint. The case was one in which a child fell down a grass bank, and the needle penetrated outside the knee. There was some difference of opinion between the child and her grandmother, as to whether the needle was there at all, because there was no mark; but immediately under the patella there was a prominence to be felt, and on using a galvanometer needle, which was even more delicate than the one which Mr. Porter exhibited, a trial was made to discover the whereabouts of the needle, and that was successful. In using the galvanometer, great care must be taken to exclude the air, and the knee must be then slowly brought to the galvanometer, as it swung under a glass shade placed upon a marble slab. Then if there was anything containing iron, the galvanometer was diverted from the zero point, and if they found that occur several times, then there could be no doubt whatever that the instrument was being acted upon by the part under examination. That was so in his case, and he cut down upon the needle and removed it. Great care must, however, be taken in using the needle; even a person walking across the room would affect it. A rather unfortunate result happened in this case; the knee-joint suppurated, and the child recovered with a stiff joint. He was not aware of the galvanometer having been used for the purpose of diagnosis before, but it was very difficult at the present day to be certain with regard to these things.

Mr. F. T. PORTER, in reply, said that in any case he considered cutting down on the needle a good practice, because it would relieve tension. He had heard Dr. Stokes allude to instances of large numbers of needles being found in cases of hysterical malingering. There was no hysteria, however, in his (Mr. Porter's) case.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
AND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER VIII.—TREATMENT: PRESERVATIVE.

THOUGH the virus of rabies may remain for a period confined to the wound in which it has been deposited, yet it is imperative that preservative measures should be promptly adopted. Fleming (*a*) points out that a fatal security might follow from a general belief in the theory of localisation of the poison for a length of time in the wound, and we thoroughly agree with his advice on the necessity of speedy action.

The first questions we have to consider are:—

Can we definitely fix the latest period when intervention might be resorted to? Have we any definite knowledge of the rapidity of absorption? Analogy does not assist us very much on this point. We know that some poisons are rapidly absorbed, and we can chemically substantiate their presence in both the blood and secretions. The poison of the viper has also been thoroughly investigated, and from the experiments of the Abbé Fontana and those of Jesse Foot, (*b*) we can almost fix the latest period when excision of the bitten part would be useful. We know with certainty that the virus of rabies is not so rapidly absorbed. We have adduced evidence of the probable arrest in the wound of the virus, an encysted or imprisoned condition, of which we have a rare example furnished in another disease. In the *Monthly Journ. of Medical Science*, 1853, (*a*) the history of a singular case is recorded:—

A girl, æt. 14, was affected with influenza. She also complained of pain in each arm, at the spots where, as an infant, she had been vaccinated. In fact, in these localities, vaccine vesicles soon became perfectly developed, and an elder sister being re-vaccinated with the lymph obtained from them, "beautiful" vesicles formed and ran a normal course.

We have not such positive evidence in regard to the localisation of the virus of rabies. Though then, as Fleming says, the prompt removal or destruction of the rabific virus must be insisted on, in order to ensure safety, yet we dare not despair of success even when it has been deposited in the wound for some time, and we are justified in resorting to preservative measures, even at so late a period as the cicatrisation of the wound. We cannot definitely fix the period or rapidity of absorption, and on this point further research is necessary.

Crucial experiments to test this point are difficult, though it might be possible to inoculate some animals with the virus, and at varying and subsequent periods, to excise the inoculated part and introduce it into another animal. Also, in case of the human subject, it might be possible, should the wound at any period exhibit an inflammatory or morbid condition, to further test the power of transmission possessed by the particles on other animals. We must then recommend those who should unfortunately be bitten by an animal to adopt precautions, and as soon as the bite is inflicted, resort to some of the measures we shall enumerate.

When the finger is burnt or pricked by a pin there is almost an instinctive feeling to put the finger to the mouth, and we shall then first consider the simplest of measures.

Suction.

This practice originated at a very early period, and was known in the time of Cleopatra, if not for rabies, as a remedy against the venom of the asp. It was rendered famous in England in the 13th century by the heroic exploit of the affectionate Eleanor, who, as history relates, safely and successfully sucked the wound of King Edward I., which had been inflicted by an empoisoned dart. (*b*) Dioscorides, (*c*) Celsus, (*d*) Galen, (*e*) Aetius, (*f*) extolled it, and Latta and Berkenhout (*g*) revived the idea, whilst more modern compilers have unhesitatingly recommended it.

Some, however, have condemned the practice, as Lipscomb, (*h*) who informs us that it is only a pleasing delusion supported by history and fable. He says, it afforded the elegance of poetic fancy, a rich theme for poetic description; but while we admire the fidelity, attachment, and heroism of those who forget the value of their own lives in the attempt to preserve their friends, we should not commend the wisdom of physicians who promise indemnity for such dangerous undertakings. (*i*) A modern physician, Sir Thomas Watson, (*j*) seems to share the needless fear of this old observer, and tells us that he dare not counsel the expedient of suction, as by adopting it the sufferer might be rushing, or bringing his helping neighbour, into the very peril he was anxious to avert.

We are diametrically opposed on this point, and must, unhesitatingly, recommend it. We agree with Fleming (*k*) that suction for the removal of poisons from wounds has been practised from time immemorial, and yet there is no evidence whatever to prove that it has been a fatal practice. On the contrary, not only has the operator in every recorded instance escaped danger, but the operation itself appears to have, in many cases, preserved the life of the wounded individual. The poison is not retained in the mouth, but is immediately and forcibly expelled, so that if there be any danger of absorption by the mouth, or by an abrasion, the chances of infection are infinitesimally small. Even though the risk was

greater than it is, it should not deter the bystander from attempting a noble and devoted act.

Performing an autopsy is dangerous, offering blood for the operation of transfusion, jumping into a river to rescue a drowning person, are attended by risk; but, fortunately, for humanity, there are volunteers always forthcoming to endanger their own lives for the benefit of their fellow-creatures.

Suction, then, should be energetically and speedily employed, either by the bitten individual or the bystander, care being taken to spit freely after each application of the mouth, and, subsequently, the mouth may be rinsed with some fluid, as water, milk, vinegar, or beer, or spirits, which are generally attainable, even though water may be scarce. It must ever be remembered, as Fleming says, that time is a most important element, and waiting for caustics, cupping-glasses, or the surgeon's scalpel may be synonymous with waiting for death.

Expression, Washing Compression, and Cupping.

Bleeding should be encouraged, and the wound squeezed and well washed with cold or tepid water, or any convenient fluid, and suction again repeated. Compression is also an old remedy, and Mosely (*a*) advises, when a person is bitten, remote from any assistance, he should make a tight ligature above the part until proper assistance can be obtained. This simple plan may be usefully adopted: it consists in tying a handkerchief, bandage, strap, or cord round the wounded part, so as to arrest the circulation; it must be applied between the wounded part and the heart; as, for instance, if the wound is on the arm it should not be applied towards the hand, but above the wound towards the elbow.

It is an adjunct to suction, washing, and other local treatment.

Cupping.—Cupping consists in applying an ordinary glass over the wound so as to promote the flow of blood; it can only be employed on certain parts of the body. An enthusiastic writer, in the "Gentleman's Magazine" for 1751, suggested that all physicians, surgeons, apothecaries, and other practitioners in physic, together with the incumbents of the several parishes throughout the kingdom, and every family in the kingdom should be provided with cupping-glasses, upon which the editor remarks, that if he did not know the author, he would be apt to think his profession was that of a glass-maker. In the same journal, same year, the bowl of a tobacco-pipe is advised to be applied, and strong suction made at the small end.

Cauterisation.

The surgeon may adopt the actual cautery, a method dating from the most remote antiquity, though the objection has been raised against it that the eschar formed on the surface or upper part of the wound might cover and shut up some portion of infectious matter, which, remaining unaltered, might afterwards produce the disease. He will of course use his judgment and modify his treatment according to circumstances.

The operator will have to consider the nature, size, and situation of the wound, whether narrow, deep, or angular, whether extensive, and whether on the face or portions of the body, where difficulties of application, from various causes, might arise. This remedy must be accurately applied, and he must endeavour to completely destroy the surfaces which the poison has touched. If the surgeon is consulted at an hospital, or at his own residence, he will have proper appliances, but, if suddenly called on, he will have to make a selection of the cautery, from some of the domestic articles found in every dwelling. If the wounds are superficial and easily reached, he can heat to a bright red or white heat a key, small poker, or any other article, and apply it freely, unsparingly, *mercifully*. If deep and narrow, he will have to select a pointed instrument, as a skewer, &c., so that it may come in contact with the deep wounded surfaces. At an hospital, and under some circumstances, chloroform or ether spray may be used, so as to render the patient insensible to pain. All the older physicians were in favour of keeping the wound open after the cautery, and were not anxious for speedy cicatrisation. Without mentioning Dioscorides, Galen, Avicenna, Ambrose Parey, we may refer to the Zurich treatment, and to the practice of Wendt and Ekstrom, mentioned in a previous chapter.

It may not be necessary to apply the irritating substances they used, but it certainly, on the evidence we have, seems preferable to keep the wound open for five or six weeks, and to encourage suppuration. The treatment of a case of rabies illustrates the indivisibility of medicine and surgery, and we may here introduce an extract from an old and experienced physician.

Dr. Moseley (*a*) remarked in 1808: "Another misfortune to humanity is, that since the separation of physic and surgery into distinct professions every physician and every surgeon is not qualified to undertake complicated cases, such as wounds from rabid and venomous animals, with their consequent diseases. A surgeon now is supposed to know as lit le of physic as possible, and a physician is supposed to know about as much surgery. What, then, must be the fate of a patient in the hands of either, who require the utmost aid of both? Hence, it is, that the knowledge of hydrophobia, and the treatment of the bites of mad dogs in particular, have not advanced with other improvements in medicine. They are as ill understood as they were in the time of Celsus; nay, worse, because Celsus was as renowned in surgery as in physic, and his method was not without great design in both."

Fleming reminds us that on occasion it may not be possible to obtain the cautery sufficiently soon, and we may have to provide a substitute. In these cases a lighted lucifer-match or fusee thrust into the wound may be very serviceable; and filling the cavity with gunpowder and exploding it appears to have proved an excellent method of cauterising dog-bites. According to M. Monière, who resided for fifteen years in Hayti, rabies is very frequent there, and appears in all seasons; but the accidents arising from it are not at all in proportion to the number of persons bitten, as every one knows what to do. Gunpowder is to be found in any house, and in nearly everybody's pocket, and is used in the manner described. Afterwards a blister is applied, and a mercurial treatment, carried to salivation, completes the case. Notwithstanding the frequency of bites from mad dogs, M. Monière has only seen one person die of hydrophobia, and that individual refused to be treated according to this plan

Excision.

We have mentioned the name of Jesse Foot, (*b*) who asserted that excision by a knife of the bitten part is the only sure and certain method of prevention, and that the sooner it be done after the bite the better. He very naively remarks that one does not want to know the utmost extent of time it will be dangerous to wait for, but one is anxious that the operation should take place as soon as possible after the accident. Foot illustrates his opinion by several cases. He claims the first case of Eliz. Pratt, as the first instance upon record where excision of the bitten part with a knife has been solely relied on..

Foot was opposed to the use of caustics in which he was confirmed by the fatal result of two cases thus treated by Mr. John Hunter, where caustic had been carefully, accurately, and freely applied. Foot insists that the sucking of the wound, the application of cupping-glasses to the part, the actual cautery, the filling it up with gunpowder and setting it on fire, the turning the wounds into an issue, the enlargement and scarification of the bitten parts are all fallible. Anything short of complete removal he considered a criminal imperfection. Lipscomb (*c*) mentions that Monro and Hunter state that the disease may be prevented by excision of the bitten part at any time before the occurrence of the second inflammation of the wound. This opinion Lipscomb condemns as replete with danger and deserving of public and solemn denunciation, for delay might sacrifice many lives which promptitude might have preserved. Abernethy recommended the following plan: The cell into which a penetrating tooth has gone must be cut out. Let a skewer be shaped as nearly as may be into the form of the tooth, and then be placed in the cavity formed by the tooth; and next let the skewer and the whole cell containing it be removed together by an elliptical incision. The removed cell must be examined, to see if every portion with which the tooth might have come in contact has been taken away, and the cell may be even filled with quicksilver to see if a globule will escape. The surgeon will use his own discretion as to the extent of the operation, and will follow out general surgical principles, both as regards the

(*c*) Lipscomb, Pamp., p. 172.

form of the incision, the depth, the use of carbolic acid, clean sponges, free washing with cold water, remembering to do his work well and thoroughly. Fleming's (*a*) remarks are very true when he says, excision is not always easy or safe because of the situation of the injury and its anatomical relations, and if a wound penetrates a joint, the eye, or other important region, the difficulty is increased. Foot (*b*) mentions the time when excision was performed in his cases, and we mention them as a contribution to our facts :—

Case I.—After 32 to 35 hours.
Case II.—After 68 hours.
Case III.—After 12 hours.
Case IV.—At once.
Case V.—After 72 hours.
Case VI.—After 20 hours.
Case VII.—After 6 hours.
Case VIII.—At once.

The knife has the advantages of facility, of the quick and immediate removal of the virus, but it requires a certain degree of skill. When surgical assistances cannot be procured we do not imagine there are many persons who would have sufficient courage to extirpate the wounded part with a knife, and there are very few who would have the resolution to cut the part out themselves—nor is it necessary if they have recourse to some of the other measures open to them. Though excision has been highly praised, and has proved almost a certain preservative, we have equally satisfactory evidence of the efficacy of the next measures we are about to consider.

Case CXXXVI.— ——, male.

Result and Time of Attack.—Six weeks afterwards. Fatal.

Treatment.—Injections of morphia, hot air.

Remarks.—Mr. Fleming considers this an illustrative case, and quotes it in his work, describing its symptoms. The patient was admitted into one of the Paris hospitals on Aug. 12th, 1869, under the care of Mr. Malherbe.

Reference.—"Rabies and Hydrophobia," p. 256. Fleming.

Case CXXXVII.—Charles ——, æt. 38, bitten on the hand by his own dog. He took no precautions as regards the wound.

Result and Time of Attack.—Forty-two days after. Fatal.

Remarks.—Dr. Deroy mentions the following as the most salient features in this case :—Intelligence definite ; consciousness of his condition ; speech jerking, and extreme agitation ; horrible difficulty in respiration ; almost continued spitting ; the sight of shining objects did not appear to irritate him (compare Romberg's case) ; but the difficulty in respiration was such that he could not tolerate any one near him ; the sight of water, wine, or any other liquids did not produce any disagreeable effect upon him ; water poured from a jug into a plate within two paces of him did not affect him. Dr. Deroy said to him, "If you cannot drink out of a glass or a cup, perhaps you can easily do so out of a saucer." But he answered sharply and angrily "I am not afraid of the liquid you offer me, but how can you expect me to swallow water or anything else when I cannot even swallow air." Does not this reply, at once so simple, energetic, and sensible, indicate that in this disease the larynx and pharynx are equally affected with the same spasmodic contractions. (Translation by Fleming).

Reference.—"Rabies and Hydrophobia," p. 251.

Case CXXXVIII.—S. B., male, æt. 27, bitten on the bare arm by a rabid dog.

Result and Time of Attack.—Three months after. Fatal.

Treatment.—Morphia, chloral, bromide of potassium, ice to the spine.

Post-mortem.—Brain very much congested, both lungs congested and emphysematous, heart normal, the other organs healthy.

Reference.—*Lancet*, p. 959. 1877. Dr. Burnett.

Case CXXXIX.— ——, male, æt. 51, bitten on the finger by a rabid dog. Finger cauterised.

Result and Time of Attack.—Five years after. Fatal.

Remarks.—Dr. Hulme remarks, "the details differ from the instances where the morbid influences of the patient's imagination simulates the real malady, and he recovers on the exposure of his delusion when the animal is proved non-rabid. Can the origin of such a convulsive attack in the saliva of a rabid dog be disputed on the ground of the long period which elapsed from the infliction of the wound? The nervous centres are quickly poisoned by serpent venom. True, a few molecules of vaccine lymph, implanted beneath the cuticle, develop constitutional changes in a fixed period. But can the remote consequences of venereal contamination be pathologically explained? At such uncertain intervals is the zymosis complete? Yet how tardily must the fermentation have taken place in the hydrophobia case related in the *Lancet* of June 30th, 1877, by Dr. Burnett, where the bare arm of a man was bitten on February 22nd, and he lost his life, after four or five days' unmistakable attack of canine madness, on May 28th ; or in another case, cauterised recently at St. Thomas's Hospital, fatal three months after! There may not be much practical advantage from pathology determining where animal poison can nestle during five years. But on what grounds can its latency for such a period be controverted? Is there not an analogy between tuberculous exudation or cancerous infiltration arriving at the active state of malignancy, and the history of *materies morbi* in human rabies finally and fatally affecting the brain and spinal column? Why should the period of quiescence be limited without suspicion to months, and a doubt be thrown upon its prolongation for a few years?"

Reference.—*Lancet*, p. 220. 1877. Dr. Hulme.

Case CXL.—Frederick John Izard, æt. 8, bitten on the face by a dog, and the wound occasioned was cauterised by a doctor.

Result and Time of Attack.—About two months. Fatal.

Remarks.—The child seemed well in health up to the 21st October, 1877, when he complained of a headache. He became convulsed at the sight of water to such an extent that it required the united efforts of four persons to restrain him. Deceased, when attended by Dr. Harrison, of Coutts Road, said that there were a lot of flies hovering around, and he refused to take drink, especially in the form of water. He foamed at the mouth and became violent, and died on the 24th October, death being, from the evidence of Dr. Harrison, attributable to the bite of a dog.

Reference.—Report of inquest, November 1st, 1877.

Novelties.

J. ALLEN & SONS' PORTABLE TURKISH, HOT AIR, AND VAPOUR BATH.

Messrs. Allen and Sons have recently introduced a very useful, simple, and inexpensive instrument, combining the means of applying the varieties of medicated air and vapour baths (mercury, sulphur, iodine, &c.). It can be arranged for local application to the chest, back, knee-joints, &c., or for general application to the surface of the body.

The lamp can be used without fear of accident, and can be easily regulated to produce any required temperature up to 160°. Apart from its value for medical purposes, it may be most advantageously applied as a bed-warmer, being more convenient, far less dangerous, and more complete in its action than the means ordinarily employed for that purpose. The whole apparatus is packed in a box, 12 inches square, with instructions as to its use, &c., for the sum of £1 10s. If medical men were to keep among their stock of instruments some such apparatus as the above, the simplicity of which enables

it to be easily understood and worked by patients, the application of medicated baths, a most reliable remedy in many skin diseases and constitutional disorders, would become a common form of treatment.

Literature.

DISEASES OF WOMEN. (a)

THESE two books, both small in size, and nominally intended for the same class of readers, are widely different as well in style as in arrangement and scope; this will appear more clearly as we proceed.

Mr. Tait's book is evidently the work of a man who has seen the diseases of which he writes, and has had the time and ability to digest what he has observed; his book is practical, and in many places he presents to his readers original observations worthy of attention. The author, moreover, throughout clearly expresses himself, and the volume is consequently agreeable reading, and we may add with truth, instructive as well as agreeable; the author has had a vast field for observation, and has worked it well. The book, however, though advertised as intended "for students and practitioners," is not by any means suitable to students, nor yet is it one adapted to the general practitioner, who requires something as a reference to guide him, where is own experience is at fault; but to the gynæcologist it is a valuable contribution, and we doubt not will be appreciated by them. The great fault of the writer is egotism; the personal pronoun "I" comes in everywhere. Even in the most trifling matters this is apparent; thus, speaking of those troublesome little bodies which spring from the orifice of the urethra, the writer says (page 52), "the most common affection of the meatus urinarius is that for which *I* have used the name of vascular growths." Why, we have known this affection by the name Mr. Tait says he has given it for quite twenty years; in fact we never thought of applying any other name to it. This vein runs through the whole book. With the exception of Mr. Spencer Wells, to whom the work is dedicated, and of Sir James Simpson, whose very errors are revered, hardly a name is mentioned. To publish a book full of authorities and replete with quotations is most objectionable, but to publish a book for "students and practitioners"—and that includes the whole profession—without any acknowlegement of how much has been done by others, is even more so.

The work, we repeat, is, as the record of one man's experience, a valuable contribution to gynæcology, but it is sadly marred by the fault we have indicated.

Very different, indeed, is Dr. Heywood Smith's book; in his preface he says, "of big books on diseases of women there is no end," the inference being that a little one is needed, and he proceeds to give us one, which is certainly not a "practical handbook of gynæcology." It is little more than a book of aphorisms, which while it may aid a student in making up answers which may enable him to scrape through an examination, will in no way add to his knowledge of gynæcology. We fear such a work is more calculated to hinder than to advance a practical knowledge of "the Diseases of Women" of which it is supposed to treat.

MR. COTTON, in the *Repertoire de Pharmacie*, says that the adulteration of santonin may be easily discovered by igniting the substance, dissolving the residue in boiling-water, and allowing it to crystallise, when boric acid separates, recognisable in the usual manner.

HEALTHY EDUCATION.

ON one or two occasions we have felt it our duty to question the soundness of certain theories and doctrines which Dr. Richardson has so frequently sought to popularise. When a man holds very extreme or decided opinions on any one subject, he is very apt to exaggerate or distort the evidence on which they are based. Hence, whether he has been lecturing on alcohol, or food, or smoking, or building of houses, or any other question connected with the wide subject of sanitation, Dr. Richardson has been often led into making statements which would be scarcely borne out by a rigorous examination of the facts on which they were founded. There are few, however, who will dispute either the propriety or the justice of the opinions to which this physician gave utterance in the course of a lecture on "Learning and Health," recently delivered by him at the London Institution. We use the word "propriety" advisedly, for education has now become such a watchword amongst us, and is being forced into so unhealthy, albeit so luxuriant a growth, that it is high time the attention of the public should be drawn to some of the errors into which our educational reformers seem likely to fall; and that the profession also should have an eye to the mischief which is too frequently inseparable from the present system of education, must be our excuse for noticing the subject in these columns.

There can be no doubt that health and education are "not going, as they should go, hand in hand." The health of the child is too often sacrificed to his education, and to the realisation of the hopes which his ambitious parents have of him. His education is conducted with too little regard to his mental capacity and physical con-

stitution. The hours of study are too long, or recreation is neither sufficient nor systematic, and the subjects learnt too many and distracting. Then there is that baneful system of cramming, which is as baneful to the learning as it is to the learner, which makes no distinction between the weak and the strong, which puts a sudden strain upon the minds of many that only the few can bear with impunity, and which, after all, produces but a show of learning that is neither profound nor exact. Now the mischief that may arise from too readily responding to the present outcry for the "higher education" of boys and girls does not, in our opinion arise from the variety or the difficulty of the subjects they are expected to master, as from the large number of youths that are indiscriminately encouraged to undertake tasks that only a few can satisfactorily perform. Under the present system, there is too little room for that principle of "natural selection" to operate which formerly produced more men of genius, although it left more dunces. Great feats of learning or of genius were more likely to be accomplished in an age when the human mind was left to its own natural bent than it is now, when, to use an apt expression of Dr. Richardson, there was more "freedom of intellectual growth." Shakespeare would probably never have shown that exquisite knowledge of human nature he possessed, had his mind been biassed by the prejudices and preconceived opinions incidental to a University education; and Bacon we know left his University at an early age, disgusted with scholasticism and the pedantry of his teachers, and determined to strike out a new path for himself. In a healthy point of view, the natural manner in which high intellectual attainments were developed was free from the objections that can be brought against much of the learning of the present day. As a rule, great intellectual power, or great genius, has always been found to be joined with a strong constitution, which was owing to the fact that the principle of natural selection being allowed more play, they alone were by nature prompted to distinguish themselves in some branch of learning, whose bodily physique was best able to bear the burden put upon it by their great intellectual exertions. This was a great matter, for as Mr. Herbert Spencer has remarked, the first requisite to attain success in life, is to be a good animal, an observation particularly applicable to those whose success depends upon exertions that involve great mental application. Hence, one of our greatest and most original living authors probably felt in his own person the importance of all men attending to their health. In the Rectorial Address which he delivered before the students of the University of Edinburgh in 1866, Mr. Carlyle dwelt much upon the supreme importance of taking care of one's health. "There is no kind of achievement you could make in the world that is equal to perfect health. What to it are nuggets and millions?' The French financier said: "Alas! why is there no sleep to be sold? Sleep was not in the market at any quotation." But if attention to health is of paramount importance to us personally, it is still more incumbent upon us to attend to the health of those who are dependent upon us, and whose healthy education is of as much importance in the interests of society and of the next generation as it is conducive to our own gratification. Yet we are now constantly seeing this principle transgressed, and young children and young girls and young men encouraged to enter upon a course of studies when they are not strong enough for it, and under the influence of which their health will inevitably break down. There is not only the system of cramming, which is so objectionable, but with regard to younger pupils, that system where young children are made to study from 9 in the morning until noon, and again, after a hasty meal, are set to work again from 1 to 4, or 2 to 5 p.m.; while later in the evening they are compelled to prepare their lessons for the following morning. With regard to the system of cramming and the rage for the higher education of women, Dr. Richardson has, like most medical men, seen many "victims to the intemperance of education." In the course of the past year four of these victims had been under the lecturer's professional care. In one case loss of memory had resulted from cramming; in another, sleeplessness and that exhaustion which leads to delirious wandering; in the third instance, over-study had aggravated an hereditary tendency to disease of the heart; and in the fourth case, the overtaxed student seemed to have been reduced to a condition bordering on insanity.

Dr. Richardson thinks that with children under 7 all teaching should be through play; but we entirely agree with a lay contemporary that this plan, which is represented by the Kindergarten system, is by no means suited to all cases, and is even defective in principle. Mixing up play with teaching spoils the one and corrupts the other, and, as a writer justly observes, that which is learned does not go beyoud loose generalisation and vague ideas. There is, however, one method of teaching young children which is rarely heard of, but which, in the case of a delicate girl, we once saw carried out with great success: it is that of oral instruction, in which the use of books on the part of the pupil is almost entirely dispensed with. In the case just mentioned, a first-class governess was engaged, and although her task was rather a difficult one, she managed in two or three years to give her pupil a good education, books being studied only when it was absolutely necessary. This, perhaps, was an extreme case, but with quite young children this system of oral instruction, conducted in a serious and systematic manner, might be more often adopted than it is.

This subject is such a wide one, and is one of so much importance at the present day, that it is impossible in the space at our command to consider it as fully as we should like, but we must at least insist upon all medical men, and especially family doctors, making it their duty to promote the cause of healthy education whenever they have the opportunity of doing so. In what does healthy education consist is a question which most members of the profession can answer for themselves, and we may on some future occasion return to the subject; but, at all events, the general practitioner, although not so often consulted on the matter as he ought to be, will frequently have the opportunity of taking care that the health of his young patients is not jeopardised by the severity of their studies and the intemperate ambition of their parents.

UNIVERSITY OF LONDON.—ADMISSION OF WOMEN TO DEGREES.

At the recent meeting of Convocation, the proposed supplementary charter to admit women to degrees in all faculties, was carried by a majority of 110 votes—242 voting in favour of, and 132 against it.

Judging from past events, and from the now almost universal expression of opinion on the part of the public in favour of the higher education of women, and of the utilisation of their thinking power, it was evident how the House would decide, though few expected that the proposed charter would be carried by so great a majority, the opinion of the medical graduates being known to be against the admission of women to *medical degrees.*

In our issue immediately proceding the meeting, we pointed out the advisability of the medical graduates not taking part in the division, inasmuch as by so doing they would, if the supplementary charter were negatived, only retard the admission of women to the non-medical examination, whereas preparation was actually being made for their admission to medical degrees under the Russell Gurney Act. It is to be regretted that the part they have taken at the recent meeting has brought down upon the medical profession the charge of trades unionism, by the daily journals. We absolve them from such a charge, and credit them with a desire to serve both the university and the public.

So far, then, as the admission of women to degrees is concerned, the discussion is virtually at an end, but there is apparently some difference of opinion among the Senate upon the question of their examination, which may be expected to give rise to a difficulty in the framing of the rules, form of examination, &c., for the conferring of the degree. If the Senate will accept our views upon the matter, such difficulty will immediately disappear. We cannot agree with Sir James Paget "that it would be a scandal and a disgrace to the University of London" to allow women to undergo the same examination as men.

To acquire a knowledge of medicine, no part of the present form of education can be omitted, and if women are to acquire a knowledge of medicine, their education must be precisely the same as that arranged for men. If the medical education of men can be tested only by the present form of examination held at the University, by such only can that of women be tested, and any difference made in the examination or any lenience shown to women, will only tend to limit their instruction and their proficiency.

At the present time, women have a medical school and a full-sized hospital in London, where women only can receive instruction and where the form of medical education differs in no respect whatever from that of the other London medical schools. They will, therefore, like men, be prepared for the examination at the University as it now stands, and it would be both unfair to the women, and in other ways unwise on the part of the Senate, to make any material difference between the examinations for the two sexes such as would give rise to the idea among the public that the examination for women was not on an equality with that for men.

Notes on Current Topics.

Mortality of Abstaining and Moderate Drinking Lives.

At the last meeting of the Society of Medical Officers of Health, a paper was read by Dr. Edmunds, entitled :— "Observations on 1,000 consecutive deaths occurring within seven years after insurance in the experience of the Temperance and General Provident Institution, with notes on the comparative mortality among abstainers and non-abstainers."

Reviewing a large mass of figures, Dr. Edmunds showed that among the 1,000 deaths which he had tabulated the mortality of the abstainers in comparison to the carefully-sifted moderate drinkers was as follows among equal numbers of insurants :—

In the gross mortality three abstainers died, where four moderate drinkers died.

Of diseases of the nervous system 70 abstainers died for every 108 moderate drinkers.

Of lung disease, 282 abstainers died for every 261 moderate drinkers.

Of heart disease, 51 abstainers died for every 47 moderate drinkers.

Of liver disease, kidney disease, and "dropsy," taken together as practically the diseases of the excretory organs, 42 abstainers died where 78 moderate drinkers died.

Of zymotic diseases, 82 abstainers died where 54 moderate drinkers died.

Of casualties, 46 abstainers died where 39 moderate drinkers died.

At the discussion to which the paper gave rise, we are not surprised that much interest and many conjectures were excited by the facts that, as shown above, the abstainers had died of lung disease, of heart disease, of zymotics, and of casualty in larger ratio than the moderate drinkers, while from nervous disorders and disease of the excretory organs their mortality had been so small. Dr. Edmunds accounted for this by supposing that persons with larger nervous energy would tax their physical frame more severely, and would run risks to life which men of less nerve would avoid. Thus the larger proportion of total abstainers died from disease of the respiratory and circulatory apparatus, in consequence of overwork, and from accidental injury, in consequence of extreme courage.

This explanation, however, appears to us extremely improbable. If any reliance can be placed upon these statistics, they rather confirm the opinions which have been generally entertained with respect to the greater tolerance of alcoholic stimulants in some diseases than in others. We would naturally expect that amongst those who were predisposed to liver and kidney affections the mortality would be greater, even of moderate drinkers, than it would be of total abstainers. While, on the other hand, from the tolerance of alcoholic stimulants which is generally shown by those who are predisposed to certain pulmonary diseases—especially phthisis—and to certain affections of the heart, we should expect that the total abstainers would more readily succumb to those affections. But the fact is, implicit reliance cannot be placed upon

the statistics which Dr. Edmunds adduced. The data are scarcely sufficient, the age of the insurants is not taken into consideration, and no allowance is made for the result of mere accident. The last mentioned fallacy is well shown by the fact that, while 46 abstainers died from casualties only 39 moderate drinkers died from the same cause. If we were to rely upon figures only we might assume that the total abstainer is more subject to casualties than the moderate drinker, which is absurd, as no one would contend that the former is more likely to fall down and break his leg than the latter.

The Metropolitan Hospital Sunday Fund.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund, was held at the Mansion House last week, Sir Sydney Waterlow, Bart., M.P., presiding. The formal business of the meeting consisted in the election of the Distribution and General Purposes Committees. The re-election of the first was moved by Sir Rutherford Alcock, who bore testimony to the financial ability with which the duties had been discharged. The latter committee, with a slight change, was also re-appointed, and on the motion of Mr. R. B. Martin, Mr. Custance was unanimously re-elected secretary. Sir Rutherford Alcock then brought forward for consideration the question of admitting the several surgical appliance societies to participate in the distribution of the Fund. The most prominent amongst these societies are the City of London Truss Society, the National Truss Society, the Surgical Aid Society, and the Provident Surgical Aid Society. The former possessed an invested fund of £30,000, and might, therefore, be excluded from the list, but all these societies were engaged in a work of essentially the same nature as that of hospitals. He submitted, therefore, to the consideration of the council whether they were not entitled to share the funds annually distributed.

The Chairman pointed out that the committee were debarred by one of the rules from giving aid to any institution except "hospitals and dispensaries," and the resolution should, therefore, take the form of proposing an alteration in that rule.

Dr. Glover urged that surgical societies fairly came within the category, and it was competent for the council to deal with them as such.

The Chairman said a similar point was raised in the earlier days of the fund, and decided in the negative. They could not now come to an opposite decision without stultifying themselves.

Bishop Claughton, Professor Marks, and others, spoke against the motion.

At present the rule stands, thus :—

"Those hospitals and dispensaries only, which are managed by a committee duly constituted, and which produce their printed reports and balance sheets, duly audited for the last three years, shall be allowed to participate in the fund."

After a considerable time spent in discussion, it was resolved, on the motion of Canon Miller, seconded by Mr. Jabez Hogg, that, "In the opinion of the council the question of admitting surgical and other kindred societies within the limits of the rule in question be referred for the consideration of the constituents of the fund."

The Health of Dublin and the Irish Provinces.

THE mortality of the city which had fallen down for one week to the level of that of the worst cities in England, has again risen and is rising. It reached last week 31·7 per 1,000 of the population, being 7 per 1,000 above Glasgow, and somewhat worse than the average mortality of the same week of the last ten years. Small-pox is becoming alarmingly prevalent, and Cork Street Fever Hospital contained 17 cases at latest report. From the Registrar-General's returns for the last quarter, it will be seen that, excluding 66 deaths in public institutions, the number of deaths registered during the quarter was equal to an annual mortality of 27·0 per 1,000 of the population, the deaths from the seven principal zymotic diseases representing an annual rate of 4·1 in every 1,000 persons. The annual rates in the several districts ranged from 16·1 per 1,000 in Rathmines, to 34·1 per 1,000 in Meath Street District; and the annual rates from seven zymotic diseases varied from 0·6 per 1,000 in Blackrock, 0·7 per 1,000 in Rathmines, to 5·0 per 1,000 in Kingstown, 5·2 Peter Street District, and 5·3 in No. 4, South City (Denzille Street and Grand Canal Street) District; the high zymotic rate in these three districts is principally due to measles; in Kingstown measles and its complications caused 20 per cent. of the deaths from all causes during the quarter, the chief mortality from the disease having been in the earlier weeks. The total death-rate for the city was 29·1, and for the suburbs 19·6; the rate represented by deaths from the seven principal zymotics being 4·6 per 1,000 inhabitants in the city (4·0 on the north side, and 5·0 on the south) and 2·6 per 1,000 in the suburbs.

The respective annual death-rate represented by the deaths registered during the quarter in the seven provincial town districts included in the weekly returns are :— Belfast 25 per 1,000 of the population, Cork 29, Limerick 23, Londonderry 16, Waterford 24, Galway 17, and Sligo 17 per 1,000. There were no deaths from small-pox registered in any of these districts. In Belfast fever caused 71 deaths, scarlatina 43, diarrhœa 36, measles 31, whooping-cough 6, and diphtheria 1; these 188 deaths being equal to an annual mortality of 4·1 per 1,000 of the population. The deaths in Cork from the principal zymotic diseases number 137, representing an annual rate of 6 per 1,000 inhabitants; they consist of 96 deaths from measles (equal to an annual rate of 4·2 per 1,000 persons), 23 from fever, 17 from diarrhœa, and 1 from scarlatina. In Waterford there were 11 deaths from measles, 8 from fever, 5 from diarrhœa, 2 from scarlatina, and 1 from whooping-cough recorded, these 27 deaths being equivalent to an annual rate of 3·5 per 1,000 persons. The registered mortality from the principal zymotic diseases in Limerick, Londonderry, Galway, and Sligo was comparatively light, and does not call for special remark.

WITH the exception of Calcutta and Madras, St. Petersburgh returned the highest death-rate last week of any city in the world from which the Registrar-General receives statistics, namely 44 per 1,000 of its population.

Hypodermic Injection of Ergotin and other Remedies in Hæmoptysis.

In the *Wien. Med. Presse* Dr. Jos. Hirschfeld makes some very practical remarks on the employment of these remedies.

Swallowing bits of ice is preferable to the external application of cold. It is aided by deep inspiration and holding the breath, except when the bleeding occurs from a cavity. The compression exerted by the forcibly inspired and retained air exercises, undoubtedly, a certain pressure upon the vascular walls and the gaping wound. With this object, Hirschfeld causes the patient to suck a cooling drink slowly through a glass tube. Internal styptics, he thinks, are of little value, and not infrequently upset the stomach. Among narcotics, digitalis is most important, especially in some cases of heart complication.

The sovereign agent, however, in hæmoptysis is ergotin, which, as is known, acts as a vaso-constrictor. Drasche was the first to use ergotin in this way in 1871. It is best administered in a glycerine solution (one to 10). To prevent any irritation from the punctnre, and to allay the irritability of the nervous system frequently present in these cases, he precedes the injection by one of morphia, or adds morphia to the solution of ergotin.

The Tincture of Veratrum Viride.

This drug appears to be a favourite medicine on the other side of the Atlantic. There are few agents, says a writer in the *Pacific Medical and Surgical Journal*, so much relied on in certain critical cases as this. The range of its application in disease is extending. It is the nearest substitute for the almost obsolete lancet. Veratrum is not one of those doubtful agents which vary indefinitely in their operation on different persons, but on the contrary its physiological and therapeutic action is almost uniform and certain. The materia medica contains no arterial sedative which can be relied on with so much confidence. There is nothing so uniformly potent in controlling priapism—a single dose being given at bed-time. Compared with digitalis, it is sure, prompt, and not cumulative. Compared with antimony, its effects are not so permanent, but it has no effect upon the character of the blood, and it does not purge. In the treatment of inflammatory affections especially pneumonia, and in acute rheumatism it has been found very serviceable. The tincture, which is officinal in the B.P., is a reliable preparation, and may be given in six to eight min. doses, every three or four hours.

The Liquor Traffic in France.

In France, according to recent statistics, the consumption of alcohol has progressively increased during the last 40 years. It was two litres per head in 1839; it is now considerably increased. The alcoholic drinks chiefly used are wine, cider, beer, brandies, and liqueurs. Wine is the national drink *par excellence*. On an average, the consumption of it per inhabitant per annum is 120 litres. But while only 38 to 80 litres are consumed per head in some departments, 360 are consumed in others. The consumption of cider is diminishing; it is about 20 litres per inhabitant. Brandy is taken to facilitate the digestion of cider, and the more cider is taken the more is taken of brandy. The consumption of beer has increased in the last fifty years. In 1823 it was about 8 litres per inhabitant; it is now about 22. The departments which consume most alcohol (spirits) are those which do not consume wine. It has been further shown by M. Lunier:—

1. That it is in the departments which consume most alcohol that excessive drinking produces most cases of accidental death.

2. That the cases of habitual drunkenness are five times more numerous in the departments which consume most spirits than in those which chiefly consume wine.

It is the same with cases of madness arising from alcohol. The proportion is almost everywhere in ratio to the direct consumption of spirits. The only exception is in La Vendée and La Charente Inférieure, which only consume white wines; and it is now known that these wines, taken in excess, are nearly as dangerous in this respect as brandies.

A Salubrious Residence.

The Omagh Board of Guardians recently prosecuted a woman for keeping her dwelling house in a dilapidated state, nearly roofless, totally uninhabitable, and highly dangerous to the lives of herself and her children.

The sanitary sub-officer said that the defendant lived in the house with her four or five children, and on the last morning he visited her she, with the children, were getting up from a bed of rushes off the floor. A large sow was lying close at hand. The defendant only laughed at him when he told her she must repair the house.

The medical officer of the district, stated that he had been in the house dozens of times, and in all his experience he never had been in such a wretched hovel. It was quite uninhabitable, and he was astonished the children had not died from cold. There was no bed in the house except a lot of rushes, and the floor was six inches deep in mud. The defendant had a snug little farm, but witness believed her to be a monomaniac. She *had a brother-in-law a clergyman, and he with her two brothers came to see her, but had not done anything for her.* Witness urged them to do something, but they walked away without doing anything. If sold, the farm would bring above £100.

The defendant was informed that a month would be allowed to have the repairs effected.

Treatment of Catarrhal Jaundice by Enemata of Cold Water.

We learn from a recent number of *La Presse Médicale* that Dr. Koull (of Gustrow), recommends this disease to be treated by injecting cold water into the rectum by means of an irrigator. The operation should be practised once in the 24 hours. The quantity of water used should depend upon the susceptibility of the individual. The temperature of the water should commence at 12° Reaumur to be decreased to 3°, as the bowel will not well bear the contact of the water when the temperature remains the same. Seven injections have been sufficient to effect a cure in the practice of Dr. Koull. This treatment removes the feeling of oppression at the epigastrium, the headache, anorexia, &c. In the majority of cases, after the second injection, the fæces are coloured with bile, and the colour of the urine becomes more natural. In the opinion of the

author, the cold water excites the peristaltic movement of the bowels, as well as the secretion of bile, the collection of which in the biliary passage is the chief obstacle to its free evacuation.

Deaths from Accidental Poisoning.

During the past year, 41 cases of fatal poisoning have been reported in the *Pharmaceutical Journal*, which though not presumed to be nearly all that have occurred in Great Britain, give some clue as to the relative frequency of the fatalities from each substance and include the most interesting cases. The cases have been from arsenic, 1 ; atropia sulphate, 2 ; carbolic acid, 8 ; chloral hydrate, 4 ; corrosive sublimate, 1 ; cyanide of potassium, 1 ; an embrocation, 1 ; hemlock, 1 ; laudanum, 2 ; mercurial powder, 1 ; " nurses' drops," 1 ; opiate draught, 1 ; opium, 3 ; paregoric, 1 ; phosphorus paste, 1 ; prussic acid, 5 ; strychnia, 5 ; and teething powders, 2. Concerning these it may be remarked that carbolic acid was administered for medicine three times in public institutions, and mistaken once for cough mixture and once for water. The sulphate of atropia was in the form of eye water and not labelled " poison." The strychnia was in three cases taken in the form of vermin killer, but in one had become mixed with santonin, and a similar accident has led to two cases of poisoning in Canada during the year.

Home Hospitals.

The *Saturday Review*, with its accustomed ability, once more discusses the question of home hospitals. For various reasons, however, the editor thinks them not very correctly designated ; the name given in no way conveys the intention or the design of these institutions. Nevertheless, if certain difficulties of management, and of a professional nature can be surmounted, they will be found to fill a decided public want. The repeated objections urged and felt by the " well-to-do," on entering hospitals supported by charity will be effectually obviated ; for it is intended to make them places in which the charges are meant to be remunerative but reasonable, and home hospitals will be made self-supporting ; and " There is at any rate one ground on which everybody must wish well to these self-supporting institutions. They ought no longer to tend towards promoting the abuse of public charities by people who can afford to pay. At present there are strong inducements towards obtaining admission to these admirable charities under circumstances which they were certainly never intended to meet. The greater chance of a cure under the best advice and most careful attendance may seem worth some sacrifice of self-respect or conscience. We have known affluent persons who have contrived to elude the rules which govern the management of these institutions, and who have either paid liberally afterwards (when conscious-stricken or when detected), or perhaps have neglected to pay at all. The establishment of the so-called home hospitals would tend to greatly discourage such abuses, and at all events it ought to make it more easy to take measures to deal with them effectually. On the whole, the scheme has our best wishes ; and, if once fairly set afloat, it might be hoped that it would in time spread from London to the rest of the Kingdom."

A German View of the British Medical Utopia.

An article appears in the *Allgem. Med. Zeitung*, which is devoted to the inculcation of unity and *esprit de corps* amongst the profession. To point the moral and adorn the tale a comparison is drawn between the recreant Germans and model English, the description of whose practice is an amusing satire. For in France and England, says the writer, pressing necessity has driven the doctors to take action together, and at the present time the public have become so accustomed to it, that no one would think of allowing the doctor to be sent for before his fee was ready for him. It never enters into the head of a doctor to pay a professional visit under any other conditions. It is well known that in England and France not a single visit is made, even to the poor, for which either the parish or the State does not pay. Never is a practitioner allowed in those countries to make a gratuitous visit. It is, therefore, only necessary for doctors to be united to get patients to make these immediate payments. It may not be brought about all at once, but with time the custom may be established.

The Use of Capsicum with Quinia.

It is not generally known that either capsicum, ginger, or other aromatics, combined with quinia, will make the patient more tolerant of large doses of this medicine, and obviate some of the disagreeable head symptoms apt to arise from its administration. Moreover, as Prof. Wm. H. Thompson has remarked, " a good dose of capsicum combined with twenty grains of quinine will act as well as thirty grains of quinine without the capsicum. Spices in general stimulate the portal circulation and promote the flow of bile, and hence their universal use in hot climates. There is a tendency on the part of quinine and capsicum to purge, and sometimes to purge violently. In such cases the purgative action is caused by the increased flow of bile produced by the capsicum. Ginger and quinine, when combined, do not purge, and it makes a very good combination. The proportions should be one grain of capsicum to three of quinine ; with ginger, one grain of each."

In malarious climates capsicum should, if possible, be preferred, as it is in itself a good stimulant, and possesses anti-periodic properties. For years we have been in the habit of prescribing a little tincture of capsicum in an ordinary quinine mixture, with the view of preventing any slight giddiness or headache that might otherwise arise from its administration.

Last week the rates of mortality in the principal towns of the United Kingdom were somewhat less than the previous week—being 24 in Glasgow, 26 in London and Manchester, 28 in Edinburgh, 29 in Bristol and Oldham, 32 in Dublin, and 33 in Liverpool per 1,000 of the populations. Plymouth gave the highest death-rate in the kingdom, namely 36 per 1,000. There were 35 deaths from small-pox in London last week, but not one in any of the provincial towns. Whooping-cough was exceptionally prevalent in Birmingham, Liverpool, and Plymouth, and scarlet fever in Manchester,

The Origin of Oxygen in the Animal Economy.

MODERN physiologists differ from those of the old school with regard to the place in the living animal organism in which the oxygen taken in in breathing, has its oxydising action: the latter, supposing it to be the blood, the former the tissues of the body. A direct proof of the new view has recently been sought by M. Oertmann in an experiment of a somewhat peculiar character on that long-suffering animal, the frog. He produced so-called "salt frogs" by injecting a salt solution (0·75 per cent.) into vascular system of the animal, an aperture being made in another part of the system, to let the blood flow off. In this way by the pumping action of the heart, all the blood can be driven out of the body, and replaced by a salt solution, and such animals will sometimes continue to live from one to two days in this state. M. Oertmann studied the consumption of oxygen and production of carbonic acid in these salt frogs, as compared with those containing blood, and fonud no essential difference, whence he infers that after removal of the blood from the frog's body, the exchange of material continues for some time in the same degree, and the place of the oxydation process is shown to be the tissues and not the blood.

Puerperal Infection of New-Born Children.

THERE are recorded three cases of this kind in *Centralblatt fur die Med. Wissenschaften.* The first was under the observation of Von Hecker, and is recorded as follows. A woman in the last stages of pregnancy was operated on for tracheo-stenosis which threatened death. Subsequent to the tracheotomy it became evident that a fatal issue would ensue from secondary hæmorrhage, and Cæsarean section was done forty hours later to save the child. The mother died, and the child, when one-and-a-half hours old, was taken into the confinement ward. It became sick on the following day with symptoms of puerperal infection, as shown by dyspnœa, high temperature, dislike of nourishment, and grayish-yellow colour of the skin, and died forty-eight hours later. The examination showed double purulent pleuritis and pneumonia. As the umbilical cord has not yet sloughed off, infectious miasm was apparently admitted by means of the respiratory function.

Kustner has collected two cases, where children, aged respectively two and three days, died of pneumonitis and pleuritis. Both children were exposed to inhalation of the discharges, which in one case were certainly putrid. One mother died on the fourth day of septic poisoning with peritonitis, the other had facial erysipelas and some uterine inflammation. It is concluded by Kustner that the lochiæ in impure air become a particularly good generating fluid for fermenting bodies, and may produce pneumonia and septic poisoning if inhaled when putrid, or if they give rise to a putrid condition in the lungs subsequent to the sojourn of the child in the impure air.

NEW YORK now contains 1,188 regular practitioners, 156 homœopaths, and 897 "miscellaneous"—unqualified practitioners. With such a tail-end, heaven help the inhabitants.

A Use in War.

AFTER all there is hardly anything from which some benefit to some person cannot be eliminated. We find the following in the *Student's Journal.*

"Students who wish to complete their sets of bones will be pleased to hear that the suggestion I made a short time ago, as to the importation of bones from the seat of war has been acted upon by at least one of the firms that cater for the wants of those who are studying anatomy, but I am not at liberty to give names or to say whether bones were obtained through Russian or Turkish agency, lest the information should reach the head quarters of the contending armies. Suffice it, that a consignment of splendid bones has arrived, and are now on sale."

Verily, this is a cogent illustration of the truth of Hamlet's speech:—

> Imperial Cæsar, dead and turned to clay,
> Might stop a hole to keep the wind away;
> Oh! that that earth which kept the world in awe,
> Should patch a wall t' expel the winter's flaw.

The "glorious circumstance of war" is fallen low indeed, when the soul of a Saracen Pasha may "suffer the rude knaves" (of Students) "to knock him about the sconce, and will not tell them of his action of battery."

Salaries of Medical Officers of Health.

A CONTEMPORARY gives some interesting data with regard to the salaries of medical officers of health, supplied by the "Medical Directory." The pay, per annum, of a medical officer of health varies from 15s. 9d, at Orsett, in Essex, to £800 at Blean, in Kent, and elsewhere. Between these two extremes there are some curious items, a few of which we give, £3 3s., £18 2s. £16 7s. 6d., &c. It would be interesting to learn on what principle the local authorities proceed to enable them to gauge the value of the services of a medical man to the tenth of a pound; but in the case of Orsett we are utterly at a loss to know what is expected of a man who receives the munificent sum of 15s. 9d. for looking after the sanitary arrangements of No. 6 district of the Orsett Union. We feel scarcely competent to decide. Mr. Clarke is also the local government officer for the same district, but his combined salary is only £3 15s. 9d., so that the inhabitants of No. 6 district have nothing to find fault with on the score of extravagance.

The Lectures at the London College of Surgeons.

PROFESSOR ERASMUS WILSON will commence a course of six lectures on "Dermatology," on next Monday, the 28th inst.; Professor Parker will deliver a course of nine lectures on the "Morphology of the Batrachia," commencing on the 11th of February; Professor Flower will then deliver nine lectures on the "Comparative Anatomy of Man," in continuation of his course of last year, commencing on the 4th of March; and in June next, Professor T. Spencer Wells and Mr. B. T. Lowne, will complete the lectures for the present year, the former by a course of six lectures, the subject of which will be hereafter advertised; and the latter by three lectures on "The Physiology of Nerve Stimulation."

Small-pox a Hundred and Fifty Years Ago.

In the *Ephemerides Medicales* of the *Union Medicale*, we find the following: 10th of January, 1722.—J. Jurin, Professor of Anatomy in the School of Surgeons in London, writes a long letter to Caleb Coatsworth, member of the College of Physicians. He communicates a table which he had prepared of the mortality of London during the 42 years preceding 1667 to 1722, comparing the mortality from all causes with that from small-pox. The following are the figures:—

Total deaths in 42 years, ...	903 798
Total from small-pox, ...	65,079
Deaths from small-pox, per 1,000 of population	72
Ratio	1 in 14

Another Death from Chloroform.

On Saturday last, an inquiry was held by the Exeter coroner touching the death of a patient whilst under the influence of chloroform in the Devon and Exeter Hospital. A very painful operation was about to be performed, and deceased, who was about eighteen years of age, had chloroform administered to him. A healthy male usually inhales from six to eight drachms before he becomes totally insensible, but when deceased had inhaled little over one drachm a spasm passed through his body, and although cold water was dashed over him, and other steps taken to restore animation, he died almost immediately. The deceased's heart had been previously examined, and there was nothing to show that he was not a fit subject for chloroform. The jury returned a verdict of Accidental Death.

The Appeal for a Poor-law Medical Officer.

The Fund which was started, with the object of relieving the urgent necessity of an Irish Poor-law medical officer, the circumstances of which will be found in our advertising columns, is about to be closed, and the money contributed will be immediately appropriated. We solicit a consideration of the case by those who have not contributed, and will be glad to receive further subscriptions within the ensuing week and before the list is finally closed.

We acknowledge receipt of £1 from Dr. Thos. Beamish, of Passage West, Cork.

Albuminuria of Nervous Origin.

M. Tessier, of Lyon, thinks that albuminuria is more often of nervous origin than is generally supposed. There are, indeed, many facts to show that nervous phenomena frequently precede the albuminuria, and that they may be considered to have some causal connection with the disease, receives some confirmation from the experiments of Claude Bernard respecting the production of albuminuria by lesions of the fourth ventricle.

Locomotor Ataxy of Traumatic Origin (?)

According to M. H. Petit, whose opinions were brought before the notice of the French Association for the Advancement of Science, locomotor ataxy has sometimes a traumatic origin. In patients predisposed to this disease some accident may probably hasten its development; but facts are still wanting in support of M. Petit's opinion. It may, nowever, be a possible and concomitant cause, not to be overlooked by those who are engaged in studying the etiology of the disease.

Bitters for Beer.

Professor Galloway, of the Irish College of Science, writes to the Dublin papers to say that his attention was directed to an advertisement which appeared in one of the journals devoted to the brewing trade of a bitter as a substitute for hops. He procured a sample of this bitter, but there was great difficulty in obtaining it, as the vendors were careful to whom they supplied it. It was found to be picric acid, mixed with a little colouring matter.

Beer, he says, was occasionally to be met with in Dublin at that time which owed some of its bitterness to that acid. But beer is not the only alcoholic liquid which requires supervision. There is at the present time a large quantity of sherry wine made which is not manufactured in the grape-producing districts, but in our cities and large towns.

Fees to Medical Men for Attendance at Poor-Law Investigations.

During the progress of a recent investigation held at the Limerick Workhouse it became necessary to call certain medical officers not connected with the institution, Dr. Holmes, Dr. Gelston, and Dr. O'Connor, and to take testimony from them with reference to the state of mind of a girl who was not under their care, and, therefore, not within their official duty. After examination the medical witnesses applied to Mr. Bourke, the Inspector who held the inquiry, for an order on the Guardians for a fee to them for attending to give evidence, which order that gentleman gave at once. The Guardians, however, refused to honour the draft when it was brought up.

The Action of Lobelia Inflata.

This medicine would be found more efficacious than it generally is in the treatment of some forms of asthma were it administered in much larger doses than most practitioners venture to prescribe. In a paper read before the College of Pharmacy of New York, Dr. Plumb denounced as erroneous the statement that lobelia in large or too frequent doses produces extreme prostration and death preceded by convulsions. He had himself taken very large doses, and he had repeatedly seen prescribed doses of one-half to two or three drachms without any injurious effects following, even when the drug had been retained on the stomach.

Professor Erasmus Wilson has now the satisfaction of seeing the object of his national undertaking—Cleopatra's Needle—safely moored in the Thames, which event occurred without further mishap on Monday. The next question to be solved is "What will he do with it"?

Sir Stirling-Maxwell, M.D., Chancellor of the University of Glasgow, died last week at Munich of typhus fever.

The "Peculiar People" again.

An inquest has been held at Southend on the body of a child whose parents belong to the Peculiar People. The child took cold, which developed into inflammation of the lungs. The parents gave it honey and gruel, but declined to call any doctor in. They told the coroner that they preferred to trust in the Lord rather than in man. They called in two elders of the church, both of whom laid hands on the child, and one, a labourer, named Angelo Chalk, also anointed it with oil. The coroner made some strong comments, and the jury expressed a hope that the guardians would prosecute the father.

Pure Water tested by Electricity.

A new method of testing the purity of drinking water, by electrical experiment, is described by Dr. Falk, of Berlin. From researches carried on in the laboratory of the School of Artillery, in Berlin, it appears that the conductive properties of water for the electric current vary rapidly according to its degree of purity, the resistance decreasing with the purity of the water. It is possible we are told, in this manner, to detect with great ease and certainty the presence of the smallest quantities of organic matter in water.

Poor-law Superannuation in France.

The Parisian Poor-law Board has recently adopted a resolution concerning its medical officers which is worthy of notice, and furthermore of imitation. Any medical officer who shall be obliged to retire from the service, either through ill-health or unavoidable misfortune, will henceforward receive an annual allowance of £48, renewable according to the exigencies of his position.

Bread for Warriors.

An Austrian military paper, the *Vedette*, states that some bread of the same kind as that issued to the Russian troops in Bulgaria, was recently obtained and examined by the military intendance in Vienna. A careful analysis showed that the bread contained 19 per cent. of sawdust, and 14 per cent. of sand.

A German paper gives a test for watered milk, which is simplicity itself. A well-polished knitting-needle is dipped into a deep vessel of milk and immediately withdrawn in an upright position. If the sample is pure some of the fluid will hang to the needle, but if water has been added to the milk, even in small proportions, the fluid will not adhere to the needle.

Professor Redwood has explained that the sign ℔ should always represent the troy pound; that lb. represents the avoirdupois pound. ℥ stands for the troy ounce (480 grains), and oz. for the avoirdupois ounce (437½ grains).

We understand that the Lord President of the Privy Council granted an audience to the Executive Committee of the General Medical Council on Friday last, with a view to Government legislation on certain medical matters.

Nottingham, it will be remembered, was selected as the place of meeting of the British Association in 1879. It appears, however, that a difficulty has arisen, and there is now a possibility that Sheffield will be selected.

The next Evening Meeting of the Pharmaceutical Society of Great Britain, will be held on Wednesday, February, 6th, 1878, at eight o'clock.

According to the report of Dr. Gilfoil, the attempted cultivation of the cinchona-tree in Australia is a complete failure, from climatic reasons.

Correspondence.

IS TYPHOID AN EPIDEMIC?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the *British Medical Journal*, Dec. 15, Mr. R. P. White, of the Meath Hospital, states that "there is a severe epidemic of, *i.e.*, typhoid fever passing over the country at present." Anything coming from Dr. White commands my sincere respect, but this statement is one so calculated, in my opinion, to do mischief, that I cannot refrain from noticing it. Believing as I do that there is no such thing as an epidemic of typhoid fever, I think such a statement calculated to divert people's minds from the true source of this very dangerous disease, viz., dirt. I firmly believe that where there is perfect conservancy, then there will be no typhoid—and this fact (for fact I look on it to be), cannot be too forcibly driven into the public mind. I know, and experience daily shows, the difficulty there is in opening the minds of even the well-educated and well-to-do people on this subject. I find water closets in the centre of houses, leaky pipes communicating with baths and slop pans; consequently, foul odours, and yet the most dire offence you can offer the proprietor is to express an opinion on their faulty construction. Until Dr. White proves the absence of all sources of contamination in the locality of those cases of which he has cognizance, I for one will not believe that typhoid fever passes over the country in epidemic waves.

I am, however, quite prepared to believe in waves of carelessness, recklessness, and reluctance to take the trouble necessary to suppress and remove the various sources from which the exciting poison may emanate. As I once heard a medical officer of the army, much occupied in India in inquiries relative to the sources of zymotic disease, say—"Good conservancy means health: neglected conservancy means cholera, typhoid, and other cognate diseases."

I am, &c.,

Portlaw, co. Waterford. J. W. Martin.

TELEPHONIC AUSCULTATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—Last night I listened to a young lady's chest with a telephone; the young lady stood in the hall, and I was thirty feet away, in the dining-room. One cylinder was placed on the chest, and the other at my ear, the connecting thread of the little toy being kept quite tense. I heard the healthy sounds of a very healthy chest quite distinctly.

Yours truly, W. B. P.

LEGALISED SALE OF POISON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is gratifying to learn that, by a recent Order in Council, that most dangerous practice, the indiscriminate sale of hydrate of chloral and its compounds, is abolished. The resolution of the Pharmaceutical Society declaring that chloral hydrate and its preparations ought to be deemed poisons within the meaning of the Pharmacy Act, 1868, has been approved of by the Lords of the Privy Council.

In consequence of a case of poisoning by syrup of chloral, which came under my care nearly four years ago, I then called the attention of the public to this crying evil, and it is surprising that it should have been suffered to exist so long.

My chief object, however, in writing this letter is, to draw attention to another abuse, the unrestricted sale of chlorodyne, a drug equal in potency to laudanum. But here, unfortunately, the stamp duty steps in legalises the sale. When is this odious tax, which may be termed blood-money, to be repealed? On the 6th of March, 1868, a meeting was convened, by the Lord Advocate of Scotland, the then member for the Universities of Glasgow and Aberdeen, for the laudable purpose of ascertaining whether the medical profession had any particular grievance which he might be the means of bringing before Parliament. I then suggested the abolition of the stamp duty, and this question was warmly and generally supported by the meeting. The only excuse advanced for the tax was, that the Government could not afford to lose a somewhat lucrative source of revenue. But this is a lame apology for trifling with the health of thousands of our fellow-creatures; and even in a monetary point of view, the sum raised by stamps on quack medicines could be easily met by a fresh duty in many other ways.

I am, &c.,

Harley Street, W., Dec. 22, 1877. J. M. Winn, M.D.

LORD CAIRNS AND HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—With reference to your leader under this title in your last issue, will you permit me to remark that I have never conversed with any medical man who has not admitted that homœopathy had so far done good, that it has all but abolished polypharmacy, and put an end to the heroic treatment of acute disease; and this indeed you also admit in your leader.

The question thus arises what is the extent of the benefit thus conferred on human beings?

Twenty-five years ago bleeding, blistering, and salivating, were considered necessary in the treatment of acute inflammatory disease, and under this treatment in our hospitals there was a mortality of from twenty to thirty *per cent.*

In our more scientific hospitals of the present day, such diseases are chiefly treated by a wise hygiene and expectancy, and the mortality has been reduced to from eight to twelve *per cent.*

I say nothing of the *positive* advantages of homœopathic therapeutics, but if the above statement is true, the only logical conclusion must be, that homœopathy has at least negatively conferred an all but incalculable benefit to mankind.

The profession is strong and noble enough to admit this, "and thus to rise on stepping stones of their dead selves to better things."

George Wyld, M.D.

Great Cumberland Street, Hyde Park, W.

THE CORONER'S INQUEST ON MR. HAYES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Re M. A. Hayes, deceased.

Sir,—In reference to an article headed "A Dublin Coroner's Inquiry," which appeared in your issue of the 15th inst, we trouble you with this letter, and will thank you to give it prominence in your next issue.

We will not occupy your space in correcting the many errors in your article—it is not too much to say it conveys an impression directly at variance with the facts, and much that you comment on never occurred at the inquest at which the writer was present.

The inquest was held by Dr. N. Whyte, of Dublin, a medical man of great experience, and the jury was one of unusual intelligence and respectability, and it numbered amongst its members a doctor of medicine and *two* lawyers. Not a jury to catch up such suggestions had any such even been made.

The Accident Insurance Company, in which the deceased was insured, were represented at the inquest by their Dublin agent and by their solicitors, and the writer attended on behalf of the family.

It is always in the discretion of the coroner to hold an inquest or not, and the conduct of the inquest in a great measure rests with the police authorities, who select some intelligent inspector for the purpose.

Now, the question of holding a *post-mortem* examination was necessarily left by the Company's solicitors and by us to the discretion of the jury, before whom several witnesses (including Dr. Brady, the medical man first called in on the discovery of the accident, and who usually attended the family) were examined carefully and freely. On hearing the medical and other evidence and seeing the body and place where the accident occurred the jury unanimously decided that the deceased had been accidentally drowned, and stated that the evidence on this point was so conclusive that they saw no reason for having a *post-mortem*, and had you been present, Mr. Editor, you had come to no other conclusion.

Dr. Croly was not produced, as the medical evidence given was unquestioned, both by the police and by the Company's solicitors, and, as the jury were satisfied, there was no reason why more money should be circulated amongst your profession.

The police-inspector who had charge of the case required Dr. Brady's attendance only, perhaps because he had first seen the dead man, and because the coroner can only certify for the fee of one medical man, and that with the sanction of the jury.

You are quite wrong in saying that the liability of the Insurance Company to pay depended on the finding of the coroner's jury; it is still quite open to them to refuse to pay, and in such case we may have a word to say with you on the subject. However, owing to the attendance of the Insurance Company's solicitors (whose medical adviser had "passed" deceased's life some two years previously), the attention of the jury necessarily was pointedly challenged to the question of death from disease or accident.

The family of a deceased person have no right to grant or withhold permission to hold a *post-mortem*. Anyone who holds such examination without the direction of a coroner's jury or of the executive is guilty of a misdemeanour, and subjects himself to unpleasant consequences.

We are, your obedient servants,

Thos. Geoghegan & Sons.

Dublin, Jan. 19, 1878.

HYDATIDS OF THE LUNG.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir.—In reference to your article on "Hydatids of the Lung" in the Medical Press of January 9th, I would draw attention to the case I published in your journal of February 21st, 1877, in which I introduced a trochar. Strange to say my patient had been in Australia for some years. I saw this patient on the 13th January, he was then in pretty fair health, but has still a spit and cough, and a small lump in the side which he says is increasing.

I remain, yours truly,

H. Talbot Higginson, M.D. Ed.

Bridge House, Bangor, Co. Down.

A NEW HOSPITAL FOR DUBLIN.

We learn with much satisfaction that Mr. John Berry, of 108 Leinster Road, Rathmines, who died last week, has bequeathed his fortune, amounting to about £26,000, and derived from large estates in the co. Kildare, to trustees for the purpose of founding an hospital at, or near the city of Dublin, for the sick poor without religious distinction. The trustees named by the generous testator are Cardinal Cullen, Mr. Theobald Purcell, Q.C., and Mr. Sergeant Sherlock, Q.C., M.P., under whose auspices we feel every confidence that his desires will be effectually

carried out. Additional hospital accommodation is much needed in Dublin; not, indeed that space or medical skill are wanting to meet the requirements of a much larger sick population than now occupy the Dublin hospitals, but because money is sadly needed to keep the beds already provided, in occupation, and to allow of the admission of very many who urgently need medical assistance, and are invariably excluded. It will be a question for the trustees to consider, with this well-known fact before them, whether they will best carry out the intentions of Mr. Berry, by adding to the accommodation for the lower classes, or by founding for Dublin a "middle class" hospital, such as has proved so successful in England in providing for a large population who are above the social rank of ordinary hospital patients, and yet not capable either of paying the medical expenses of a long illness, or maintaining themselves when thrown out of employment by continued illness. The numerical importance, and the urgent wants of such classes in the way of hospital care in a city like Dublin, must be obvious, and we hope the trustees may—if the option is allowed them by the terms of the will—consider from this point of view the appropriation of the bequest.

We believe that the testator has manifested his gratitude to his medical attendant, Dr. Hepburn, of York St., by designating him one of the medical staff of the institution, a choice which secures to the hospital a valuable and most zealous officer. The bequest is the most valuable one which the sick poor of Dublin have received since the death of Mr. Egan, of High Street, and the amount is sufficient to provide and endow an institution of great value to the community.

EXAMINERS FOR THE QUEEN'S UNIVERSITY.

The election of examiners for this university is announced to take place on the 1st of March, the following being the subjects attaching to each examinership:—Medicine, surgery, midwifery, materia medica, and medical jurisprudence.

The holders of office at present are the following:—

Medicine—Benjamin G. M'Dowell, M.D.; H. Charlton Bastian, M.R.C.S.E. *Surgery*—Anthony H. Corley, M.D.; William Stokes, M.D. *Materia Medica*—Charles F. Moore, M.D.; Prof. Pye, M.D.; *Midwifery*—William Roe, M.D.; John Guinness Beatty, M.D. *Medical Jurisprudence*—Matthias O'Keefe, M.D.; William Stoker, M.B.

These appointments are tenable for two years. The emolument for medicine and surgery is £100 per annnum; for midwifery and medical jurisprudence £75 per annum,

The Etiology of Typhoid Fever in Soldiers.

Soldiers, from their position and the facilities for observations concerning them, should afford opportunities of clearing up disputed points in the etiology of many diseases. M. Leon Colin has devoted his attention to the etiology of typhoid fever in the French service. Some of his conclusions are:—

1. The predominance of typhoid found in the army depends on the degree of receptivity, special to numbers of men, young and robust, and unaccustomed to large towns. If you take away from the population of a small place children, old men, and, in a word, all those persons who are for various reasons unpredisposed to this affection, you evidently increase the chances of its attacking those for whom it has a selective affinity. These chances reach their *maximum*, if the population thus reduced are submitted to such influences as are common in large towns. 2. The actual increase of mortality in the French army from typhoid fever is not the result so much of military insalubrity, but of the increased proportion of young soldiers specially inclined to this affection. Supposing the number of children per troop were notably increasd, the medical statistics of the army would establish the greater frequency of affections common to infancy, as croup, diphtheria, whooping-cough, but the *casernes* would not therefore be incriminated, as being more favourable than formerly to the genesis of these affections. If, then, typhoid fever finds an easier development in the army on account of the young element, the number of affections special to old soldiers may be diminished. Statistics prove a marked and compensating decrease of pulmonary phthisis, since the total mortality of the army from year to year continues to diminish. 3. The relative immunity of armies in the country proves that the extreme receptivity of the soldier is not sufficient for the spontaneous generation of the malady, the most probable cause of which is the poisonous emanations in the atmosphere of large towns.

Medical News.

College of Physicians in Ireland.—At the examinations held this month the following obtained the licenses in Medicine and Midwifery:—

Medicine.—John Leonard Aherne, Henry Armstrong, Thos. Francis Arthur, Annie Reay Barker, Bartholomew Madigan, Joseph Michael Redmond, Richard Foster Owen, Arthur Leggo Roe, William Ribton Spowart.

Midwifery.—John Leonard Aherne, Henry Armstrong, Thomas Francis Arthur, Annie Reay Barker, Bartholomew Madigan, Joseph Michael Redmond, William Ribton Spowart, Joseph Fitzhenry Woodroffe.

Society for the Relief of Widows and Orphans of Medical Men.—The Quarterly Court of the Directors of this Society was held, last week, in the rooms of the Royal Medical Chirurgical Society. The chair was taken by Dr. Pitman, V.P. The sum of £1,238 was voted to be divided, according to their circumstances, among 60 widows, a sum of £55 was distributed to 12 orphans, and £25 10s. was given from the Copland Fund to 4 applicants for assistance. The expenses of the quarter amounted to £39 1s. 3d. The Treasurer informed the court that the Christmas present had been distributed on Dec. 17th, among 58 widows and 14 orphans, and was received with much gratitude, the amount given was £326. Fresh applications for grants were accepted from 2 widows and 2 orphans. Six new members were elected.

Growth of Population.—It is now nearly seven years since the last census was taken, so that the population returns then presented would now be far from correct were they taken as the basis of calculation by the Registrar-General and local authorities generally. In the absence of actual returns, therefore, the Registrar-General is in the habit of estimating, as nearly as he can, the various populations at the middle of each year, starting on the assumption that the rates of increase show on comparing the two last census returns remaining in force. In two towns, namely Salford and Oldham, this course has been departed from, and local information is taken in its stead. London is estimated by the Registrar-General to have increased from 3,254,260 in 1871, to 3,577,304 in 1878. Similarly Brighton is estimated to have risen from 90,011 to 103,923; Portsmouth, from 113,560 to 129,461; Norwich, from 80,386 to 84,620; Bristol, from 182,552 to 206,419; Wolverhampton, from 68,291 to 74,240; Birmingham, from 343,787 to 383,117; Leicester, from 95,220 to 121,473; Liverpool, from 493,405 to 532,681; Manchester, from 351,189 to 360,514; Bradford, from 145,830 to 184,088; Leeds, from 259,212 to 304,948; Sheffield, from 239,946 to 289,537; Hull, from 121,892 to 143,139; Sunderland, from 98,242 to 112,459; and Newcastle, from 128,443 to 144,596. The recent great alterations in the boundaries of the borough of Nottingham have altered

the population very greatly, so that, while the number of inhabitants in 1871 was 86,621, there are now estimated to be no less than 165,267; the population of Salford has risen from 124,801 to 170,251; and Oldham from 82,629 to 107,366; Manchester and Salford together certain, it is calculated, 530,765; thus differing very slightly from Liverpool. The density of these populations varies greatly, namely, from 11·3 persons per acre in Norwich, to as many as 102·2 in Liverpool. They stand in order thus:—Norwich 11·3, Leeds 14·1, Sheffield 14·7, Nottingham 16·6, Wolverhampton 21·9, Oldham 23, Bradford 25·6, Newcastle 26·9, Portsmouth 28·9, Salford 32, Sunderland 34, Leicester 38, Hull 39·4, Brighton 44·1, Birmingham 45·6, Bristol 46·4, London 47·5, Plymouth 52·8, Manchester 84, and Liverpool 102·2 per statute acre.

Hydrophobia in Cheshire.—Another death was reported yesterday at Over in Cheshire, making four from hydrophobia within three weeks in the same neighbourhood, where intense excitement exists in consequence.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after i has passed through the post.

THE HONBLE. GRANTLEY BERKELEY.—Communication received, and will be considered.

MR. G. R. J.—Your letter, requiring an answer which could only be given in one quarter, was duly forwarde d on its receipt; but no reply had arrived at time of our going to press.

A RADICAL SANITARIAN.—Your letter is too political, though we shall quote a few lines from it:—"The future of Ireland and of her people must be considered hopeless so long as our Legislature is indifferent to our sanitary requirements. Overcrowded dwellings, impure air, deficient scavenging, bad drainage, with a train of disease, dirt, and poverty are not conducive to either the moral or the material prosperity of any country. Agitators should preach the gospel of cleanliness and thrift; and clergymen, in place of dogma and theological definitions, the Evangel of temperance; whilst corporate authorities should be compelled to perform their duty."

IN our issue of the 9th inst. was a paragraph on the "Treatment of Obesity by Bladder Wrack or Fucus Vesiculosis," the fluid extract of which was mentioned as an American preparation. Messrs. Corbyn and Co. have forwarded us a sample of the fluid extract (dose 3j.) which they have been supplying for some years past.

THE OPPONENTS OF THE CONTAGIOUS DISEASES ACTS.—Our readers will remember that a few weeks since our "Correspondence Columns" were occupied in a discussion on the merits and demerits of the Contagious Diseases Acts. We gave space, as is our wont, to both sides, until great pressure of other important matters compelled us to close the discussion. We are surprised, therefore, to find in the last number of the *Medical Enquirer* (organ of the Acts' opponents) "letters which had been refused insertion in the MEDICAL PRESS AND CIRCULAR." One of these letters *appeared* in our issue of Dec. 19 (minus the quotations from the Rescue Society, whose statistics are not generally acknowledged), the other had already appeared in substance, and as we were compelled to close the discussion we could not afford space to repeat it. As conductors of a public organ of the profession we are quite impartial in the matter, and, as a matter of fact, we inserted more letters against the Acts than for them. We are astonished, therefore, to find that the opponents of the Acts do not act fairly or truthfully towards the only medical journal (MEDICAL PRESS AND CIRCULAR) which has allowed them to ventilate their opinions, and are forced to the conclusion that they, like the opponents of most legal measures, the anti-vaccinators, anti-vivisectors to wit, can see no good out of their own narrow circle, no truth beyond the pale of opposition.

CLINICAL SOCIETY OF LONDON.—Friday, Jan. 25th, at 8½ p.m., Mr. Pearce Gould, "On a Case of Spina Bifida cured by Injection of Iodine" (a living subject). Mr. Berkeley Hill, "On Cases of Spinal Curvature treated by Sayre's Plaster Jacket (living subjects). Mr. Nunn, "On two Cases of Cancer of the Breast." Dr. Broadbent, "On a Case of Paracentesis Thoracis."

A CANDIDATE FOR THE SERVICE will find the information he requires on reference to our advertising columns. The list of candidates for appointments will be closed February 2nd.

PREMATURE.—We do not know if the following, which appeared in last week's *Sheffield Telegraph*, and subsequently copied into the leading daily papers, is intended as a joke upon the medical profession. If true, the practitioner who was guilty of such a rash act is probably suffering as he deserves to be from considerable mental depression and loss of appetite: "A poor woman lay very ill in her scantily-furnished home in Sheffield. The doctor was sent for and came. He at once saw that here was a very grave case, and that she had, he thought, little chance of recovery, even if she could get the nourishments her illness required. As he was about to leave, the question was put, 'When should we send for you again, doctor?' 'Well,' was the reply, as he looked at the poor woman, and then at her wretched surroundings, 'I don't think you need send for me again. She cannot possibly get better; and, to save you further trouble, I'll just write you out a certificate for her burial.' And he did. After the doctor departed, the woman—women always were wilful—get rapidly better. She has now completely recovered, and goes about carrying her burial certificate with her."

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED

Lectures on Diseases of the Nervous System. By S. Wilks, M.D London: J. & A. Churchill.

The Retrospect of Medicine. Vol. LXXVI. Edited by Drs. W. and J. Braithwaite.

Dédoublement de la Personnalité. Par le Dr. Azam, Bordeaux.

Sanitary Report of Wandsworth for 1876.

On Ringworm. By Tilbury Fox, M.D. London: Henry Renshaw.

St. Bartholomew's Hospital Reports. Vol. XIII. London: Smith, Elder, & Co.

The Westminster Review. Revue Scientifique. Le Progrès Medical. Clinic. Dental Journal. Obstetrical Journal. Glasgow Medical Journal. Paris Medical. Glasgow University Magazine. Home Chronicler. Temperance Record. Students' Journal. New York Medical Record, &c., &c.

VACANCIES.

City of London Hospital for Diseases of the Chest.—Assistant Physician. Honorary. Candidates must address the Treasurer by the 26th inst. (See Advt.)

Ipswich Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board and lodgings. Applications to Dr. Chevallier, Medical Superintendent.

Limerick Union Workhouse.—Resident Medical Officer. Salary, £100, with allowances. Election, Jan. 30.

Mountmellick Union, Clonaslee Dispensary.—Medical Officer. Salary, £100. Election, Jan. 24.

Northampton General Infirmary.—Physician on the Staff. Testimonials, &c., to the Secretary at the Infirmary.

Nottingham Dispensary.—Resident Assistant Surgeon. Salary, £160. Applications, with testimonials, to the Secretary Broad Street, Nottingham.

Queen's University, Ireland.—Examiners in Medicine, Surgery, Midwifery, Materia Medica, and Medical Jurisprudence. (See Advt.)

Royal Free Hospital.—Two Junior Resident Medical Officers. Board and residence provided, but no salary. Applicants must address the Secretary before the 30th inst. (See Advt.)

Wilts Pauper Lunatic Asylum.—Medical Superintendent. Salary, £600, with furnished apartments. Endorsed applications, "Medical Superintendent," before the 12th February, to be addressed to the Clerk of Committee, Devizes.

Births.

DAVIES.—Jan. 14, at Pembridge Villa, Bayswater, the wife of Dr. Gomer Davies, of a daughter.

HARDING.—Jan. 14, at 6 Upper Fitzwilliam Street, Dublin, the wife of Surgeon-Major Harding, F.R.C.S.I., Army Medical Staff, of a daughter.

SMITH.—Jan. 15, at 2 Portugal Street, Grosvenor Square, W., the wife of Heywood Smith, M.D.Oxon., of a son.

Marriages.

ANDERSON—ANGELL.—Jan. 17, at St. George's Hanover Square, W., J. W. T. Anderson, L.R.C.P., L.R.C.S., to Katherine, daughter of T. J. Angell, solicitor.

BROWNE—GRANT.—Jan. 9, at St. Peter's, Hammersmith, J. Walton Browne, B.A., M.D., eldest son of Dr. S. Browne, of Belfast, to Matilda Elwin, second daughter of the Rev. F. B. Grant, M.A.

SYKES—STAINES.—Jan. 16, at the Parish Church, Marylebone, William Sykes, M.R.C.S., of Mexborough, Yorks, to Kate, youngest daughter of the late Richard Staines, of Harewood Square, London.

THOMAS—DAVEY.—Jan. 1, at St. John's Church, Clifton, Lewis W. Thomas, of Highbury, to Edith Constance, eighth daughter of J. G. Davey, M.D., of Northwoods, Bristol.

THOMPSON—ORPIN.—Jan. 8, at Kendlestown, co. Wicklow, Robert Norman Thompson, M.B., Kilquade, co. Wicklow, to Helen Constance, elder daughter of William Basil Orpin, Esq., Kendlestown, co. Wicklow.

WRIGHT—FINLAY.—Jan. 3, at Monkstown, co. Dublin, Wm. M'Dowel Aikin Wright, B.A., M.B., Braganza, Dalkey, to Emily, second surviving daughter of George W. Finlay, Local Government Auditor, Hybla, Kingstown.

Deaths.

ALLWOOD.—On board the outward bound Ship *Northumberland* to Melbourne, John P. Allwood, L.R.C.P., M.R.C.S., Surgeon in charge, aged 33.

BLUNDELL.—On Jan. 15, at Piccadilly, James Blundell, M.D. aged 87.

CLARKE.—On Jan. 9, at Lynton, Devon, John Clarke, M.R.C.S.E. aged 80.

ELLIOT.—On Jan. 7, of cholera, at Chowringhee Road, Calcutta, Surgeon-Major John Elliot, M.D.

HOLT.—On Jan. 11, at Uckington, Cheltenham, Joseph Rose Holt, M.R.C.S.E., aged 85.

KERR.—On Jan. 12, at The Hale, Newnham-on-Severn, William Charles Kerr, M.D., aged 78.

LYALL.—On Jan. 13, at Lennoxtown, Stirlingshire, William Lorimer Lyall, M.D.

IRISH POOR-LAW INTELLIGENCE.

FILTH REMOVAL.

THE Local Government Board for Ireland has placed before the sanitary authorities in Ireland the following facts in relation to the subject of filth removal.

It appears in the last report of the English Local Government Board that from the year 1848 to the present time, a period of almost thirty years, sanitary works for the two purposes, chiefly of sewage and water supply, have been carried on with the aid of loans, supplied, at first, from various sources, but in recent years almost wholly from Imperial funds; and that in 1877, the date of the report, no less a sum than £38,750,740 of debt remained outstanding, charged on local rates on account of such loans. The greater part of these loans were raised in the latter part of the period mentioned, and they are now proceeding at the rate of £5,000,000 per annum.

Similar operations in Ireland became available since the Sanitary Act of 1866, a period of eleven years, but were little resorted to until the passing of the Public Health Act, 1874, since which time much activity has been shown in contracting loans to construct works for sanitary purposes.

A considerable part of this expenditure in England has been made upon works of irrigation and sewage farms, more especially in towns ranking in the second or third class, or even in still smaller classes of towns, of which there are a great number in England, each with its own governing body.

Such expenditure has, from various causes, not always been attended by success, even where the experiment has been apparently made under suitable circumstances. Nevertheless, in the report of Messrs. Clare Reade and Rawlinson, many cases of comparative success will be found—that is to say, cases in which the utilisation of town manure on sewage farms has gone far to meet the expenses of filth removal.

It is not always, however, that sufficiently favourable circumstances exist to justify the governing body of a town in making trial of a sewage farm or of irrigation works for this purpose. Some examples of unequivocal success are, however, to be found in the report.

The sanitary history of Liverpool begins with the earliest time of sanitation in Great Britain, and has been associated throughout the whole period with a very high death-rate in comparison with other towns.

Throughout that period one mode of filth removal has been persistently carried out—that is to say, the gradual suppression of the midden-steads and blind cess-pools, and the substitution of water-closets and trough-closets, with a corresponding system of drains and sewers.

In the year 1854 a local Act was passed for Liverpool, under which the substitution of water- and trough-closets for middens was vigorously carried on, at considerable cost, by the corporation; and in 1876 it is found there are 70,000 water-closets and 3,710 trough-closets, while the number of middens remaining are 14,012.

These operations, with other sanitary improvements, have not been without their effect on the death-rate of Liverpool, which, in 1876, was 27·5, in comparison with 30·7 as the average of the previous ten years.

When the Liverpool water-closet and sewer system shall have attained the utmost perfection of which it is capable, there must always remain the large continuous operation of scavenging such of the dry refuse as could not be passed through the sewers. At present many middens still remain to be dealt with by the scavengers, and the annual cost of the whole, including the watering of the streets, in 1876 was £74.563. The receipts for manure sold were only £8,690.

The sanitary history of Birmingham is as different from that of Liverpool as the difference between two such towns could possibly be, only 7,065 water-closets existing at Birmingham in comparison with 70,000 at Liverpool, although the difference in population is only as 35 to 50. The course of action at Birmingham has been subject to much variation, attended by great expenses. The first operations were in the construction of drains and sewers into adjacent streams. This resulted in the authorities being restrained by the Court of Cancery from further pollution.

Utilisation of the sewage by means of sewage farming was the expedient next resorted to, but, if at all successful, it has been so only in a small degree, and to a small extent.

In the year 1873 the pail system, for some time previously in operation at Rochdale and Manchester, attracted attention at Birmingham. Since its introduction at that date the number of pails has increased to no less than 20,000 in the year 1877, and is still increasing at the rate of 200 per week. This form, therefore, of filth removal appears to be likely to become the general system of Birmingham, after the example of Manchester, where, having been commenced in 1869, it is now more nearly advanced to general adoption.

One important feature of the pail system as practised at Rochdale and Manchester, is the periodical collection not only of the fæcal deposits from the entire area of its operation, but also of all dry refuse from the ash-tubs associated with the pails, which, in bulk, forms the larger portion of the refuse of all towns.

The modes of disposing of the dry refuse at Rochdale and Manchester have been previously described; but at Birmingham a new kind of machinery is in operation, patented by Mr. Fryer, the inventor, for the wholesale destruction by fire of otherwise useless *débris*, deriving from the incinerated mass a valuable description of charcoal, and, at the same time, applying heated gases to the evaporation of moisture from the fæcal deposits, without occasioning the loss of the ammonia which so greatly enhances the value of the manure.

The resulting product, although obtained by a different process, is nearly identical with that manufactured by Liernur's process, and called Poudrette, which has been shown to be a manure dry and portable, and of a high chemical value.

Mr. Fryer's method of obtaining a similar manure, assuming it to be of equal chemical value, appears to deserve attention from the governing bodies of towns which have not yet entered upon the introduction of any general system of domestic scavenging, because, in the first place, its action is comprehensive, providing, as it does, for the removal and utilisation or destruction of every kind of town refuse; and, secondly, because the only aid it demands in the collection of its materials is the construction and scavenging of pails and ash-tubs, as economical a mode of collection as any other, and not involving, under any circumstances, a pollution of streams or of well-water, or any saturation of the soil with matters injurious to health.

How much Ireland is behind England in sanitary progress is more observable in relation to filth removal from towns than

in any other respect, for while in the latter country various modes have been in course of adoption for many years past, with more or less success, we are in this country now only at the beginning of such operations, comparatively, and the first task which now presents itself to the Irish sanitary authority is to see the lower classes of the population furnished with some provision for domestic cleanliness which may admit of prompt mode of removal. Where a total absence of all conveniences exists a grave error would be committed by attempting to remedy it by the use of midden-steads, which English example shows to be a remedy worse than the disease, and which would have to be replaced at much expense by other contrivances hereafter. At present the two alternatives appear to be some form of water-closet or some form of pail-closet.

THE CRIPPLES' HOME AT BRAY.

UNION PATIENTS AND THE LEGALITY OF THEIR MAINTENANCE.

THE Chairman of Quarter Sessions gave last week his decision in the case of the Ballymoney Guardians against the auditor of the Local Government Board, which had come before him by way of appeal from the decision of the magistrates. The facts of the case were these :—A young girl who was suffering from a severe spinal complaint, had been sent to the Cripples' Home, at Bray, by the Guardians of the Ballymoney Union, at a cost of somewhat under £3, which they had defrayed out of the rates. The auditor in taking the accounts had disallowed this item, on the grounds that the Cripples' Home was not an hospital within the meaning of the special Act under which the guardians had purported to act ; and the guardians, having refused to refund the sum disallowed, believing that they had acted within their powers under the above Act, the auditor summoned them before the magistrates, and obtained an order for payment. From this order the guardians had appealed. The attorney for the respondent objected to the hearing of the appeal, inasmuch as there was no provision under the Poor Law Acts for making such appeal to the Court of Quarter Sessions. In the course of a lengthened and able address, the Chairman, shortly after the sitting of the court yesterday, decided to reverse the order of the magistrates, on the ground of its informality, as well as upon the merits of the case, holding that the guardians had acted within their power. The Chairman commented severely upon the argument which had been advanced on behalf of the auditor, that the Local Government Board were the sole arbiters, touching the construction and meaning of the Act of Parliament relied on.

COOKSTOWN BOARD OF GUARDIANS.

THE Chairman having read the circular convening the meeting, "to consider the application of the medical officer of the workhouse for an increase of salary,"

Mr. Gunning said he begged to move that Dr. Hamilton's application be granted, and that his salary be increased £20. It would be a mere trifle when spread over the union. Mr. Gunning (continuing) referred in complimentary terms to Dr. Hamilton's long services for a period of thirty-five years, and remarked that the Sanitary Act had made an addition to the salaries of the other medical officers, but had not benefited Dr. Hamilton in the least.

Mr. M'Entire wished to know what was the salary at the commencement.

Clerk—£40.

Mr. M'Entire—I thought so, but it has been increased more than once.

Clerk—It was afterwards raised to £50 ; some years after to £60, and then some time after reduced to £50, and in 1866 it was increased to £80.

Mr. Gunning—Gentlemen, I have showed you that the increase will not make a difference of a fourth of a farthing on the rates, and I now propose that the £20 be granted.

Dr. Charles seconded the motion. They would all concur with Mr. Gunning's remark as to the great attention that Dr. Hamilton had at all times given to his duties. (Hear, hear.)

Mr. Stanley moved that £10—the salary allowed to the consulting sanitary officer—be added to Dr. Hamilton's salary.

There were then three polls taken, the final one being on the original motion and amendment, when the numbers stood thus :—For the amendment 9, for the motion 14.

THE SANITARY ACT IN BALLINASLOE.

AT the meeting of the Ballinasloe Town Commissioners attention was drawn to the neglected state of the water works and market house.

The Chairman.—It is not our business to see after it at all, but it is the duty of the board of guardians. It is a farce to see the manner in which the sanitary business has been carried out. When we were the sanitary authority we saw the arrangements properly carried out.

Mr. Sharpe.—It is a disgrace to the town.

After much discussion a notice of motion was handed in to the effect that a memorial be presented to the Government praying that a bill be introduced at the approaching session of Parliament to transfer the sanitary powers from the guardians to all bodies of town commissioners irrespective of population.

DROGHEDA UNION.

THE SANITARY ACT.

A CIRCULAR letter was read on the subject of filth removal, urging on local bodies more energetic steps in dealing with the Sanitay Act.

Mr. Everitt—The supreme authorities for carrying out the Sanitary Act, which ought to be one of the most important to the community, may save themselves the trouble of sending circulars about it until they became more energetic themselves. The act has lapsed into a complete humbug in their hands. They may put their Sanitary Act in their pocket; it is only a humbug ; a means of raising salaries.

STRANGERS AT MEETINGS OF POOR-LAW GUARDIANS.

AT Mountmellick petty sessions last week, a member of the board of guardians summoned Denis Feighery, contractor to the board, for not leaving the board room when desired so to during the proceedings on a recent occasion. The summons was based on a sealed order of the Poor-law Commissioners, dated 1840, whereby a party so offending is liable to a penalty of £5. One of the magistrates said that it was most uncalled for to summon the defendant, and the case was dismissed.

ENNIS DISTRICT LUNATIC ASYLUM.

PAYING PATIENTS.

UPON the subject of paying patients and the Treasury Grant the following minutis was agreed to :—

"In reply to the letter of the Privy Council 4th January, 1878, the Government of the Clare Lunatic Asylum at meeting this day request that the inspectors inform us if patients contributing to their maintenance be entitled to receive the Parliamentary grant of 4s. per week from the Treasury and what amount of contribution would disqualify paying patients from the grant."

Dr. Cullinan said he had received a letter from Dr. Nugent on the subject, which stated that if a patient does not contribute more than £14 a year the Board are entitled to get £10 Treasury grant, but when it exceeds that sum, no contribution will be given.

VACCINATION PROSECUTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to bring to the notice of your paper the following case of attendance at a Petty Sessions Court, so as to get your opinion, or of some of your readers, on it.

I had to report a case of neglect of vaccination to the Poor-law Guardians. The parent of the child refusing to have it vaccinated, was brought before the Petty Sessions Court, and was fined under the Vaccination Act. I had to attend as the witness; the parent still refusing to vaccinate was again brought before the same Court, a fine was recorded, but not enforced, as it was found out that a person could not be prosecuted under the Vaccination Act a second time for the same case. I was again the witness next time the parent was prosecuted under the Sanitary Act; this was dismissed for some informality in the notice; I attended this third time as witness. Again the parent was summoned under the Sanitary Act, and was given a certain time, within which he was to have the child vaccinated; this fourth time I attended as witness. Again the time having expired which was given, the parent was brought before the same Court, and at his request the case was adjourned for a fortnight, so as to enable him to have the assistance of professional counsel. This is the fifth time I attended the Court as witness in the same case; the last two occasions I was served with regular summons to attend.

I applied now to the magistrates for an order for a fee for my attendance, and was refused, as I am the dispensary officer and sanitary officer of the district, and as such it was considered part of my duty to attend as witness.

I consider this is a hard case, so much of my time being taken up for one vaccination case, the pay for which, if I vaccinate, will be one shilling.

Your obedient servant,

EDW. B. DORMAN, M.D.,
Medical Officer and Sanitary Officer,
Kinsale Dispensary.

Kinsale, 5th January, 1878.

[If our correspondent will call the attention of the magistrates to the definition of his duties as dispensary medical officer, which he will find set forth in Article 22 of the Regulations (page 245 "Irish Med. Directory for 1877), and to the terms of the Medical Charities and Vaccination Acts (pages 494 and 497); also to the definition of his duties as sanitary officer (page 544), they will, we are sure, be satisfied that vaccination prosecutions is not any part of his official duties. The Local Government Board has repeatedly recognised the giving of evidence in such cases as an extraneous matter to be paid for by an extra fee, and Parliament has recognised it as such by giving the magistrates a special power to order a fee—Vac. Amendment Act, 26 & 27 Vic., cap. 52, sec. B., page 498. It is left in the discretion of the magistrates to order the fee, but it is also entirely in the discretion of the medical officer to give his professional evidence. If he declines to attend as witness he may be required to go by means of subpœna, but when asked his professional opinion as to the efficacy or desirability of vaccination in any particular case he may refuse to give it unless his fee is guaranteed. As it is above all things desirable that the vaccination system should be efficiently worked, we do not advise any medical officer to adopt this course except in extreme cases and as a matter of important principle, but it is, nevertheless, open to him to do so.—ED. M. P. & C.]

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING JAN. 12, 1877.

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 36; average number in the second week of the last ten years 39. Among the deaths from these causes are 5 from fever (1 typhus, 2 typhoid and 2 simple continued fever), 11 from measles, 5 of which occurred in Meath Street District, where but few deaths from this cause had been recorded in recent weeks, 9 from whooping-cough—an increase of 3 on the number in the first week of the year,—3 each from croup and diarrhœa, 1 each from scarlet fever, dysentery, &c. Of the 36 deaths from zymotic diseases 26 were amongst children under 5 years of age.

Fourteen children died from convulsions.

Bronchitis caused 44 deaths, pneumonia 11, and pleurisy 1; these 56 deaths are 7 over the average number of deaths from diseases of the respiratory organs in the second week of the last ten years.

Seven deaths were attributed to heart disease, 1 to aneurism, 6 to paralysis, 3 to apoplexy, 1 each to epilepsy and brain disease unspecified; and 2 each to Bright's disease and kidney disease unspecified.

Thirteen deaths resulted from phthisis, 3 from hydrocephalus and 1 from cancer.

BELFAST.—Six deaths from fever, 2 from scarlatina, 1 from whooping-cough, and 4 from diarrhœa were registered during the week.

CORK.—Eight deaths from measles, 3 from whooping-cough, and 2 from diarrhœa were registered.

LIMERICK.—Two deaths from measles and 2 from scarlatina were registered.

WATERFORD.—Eleven deaths from measles were registered; the Registrar remarks "Measles prevalent, but on the decline."

QUARTERLY SUMMARY.

Births.—In the Dublin District the number of births registered during the quarter amounted to 2,201, being equal to an annual ratio of 28·0 in every 1,000 of the population.

The number in the city was 29·8 in every 1,000, and in the suburbs 21·6.

There was registered in London during the same period 36·1 in every 1,000, in Glasgow 36·2, and in Edinburgh 33·3.

Deaths.—The number of deaths registered in the Dublin district during the quarter amounted to 2,192, affording an annual ratio of 27·9 in every 1,000 of the population; the average number in the fourth quarter of the previous ten years was 1,946.

The deaths north of the Liffey were 27·9 in every 1,000, south of the river 30·1, and in the suburbs 19·6 in every 1,000.

The number of deaths registered in London was 22·3 in every 1,000 of the inhabitants, in Glasgow 22·7, and in Edinburgh 21·8.

Diseases.—Dublin Registration District.—The deaths from zymotic diseases registered during the quarter number 436, or 19·2 per cent. of the total deaths, and equal to an annual rate of 5·6 per 1,000 of the population; the average in the fourth quarter of the previous ten years was 434. The deaths last quarter from the seven principal diseases of this class represent an annual mortality of 4·1 per 1,000 inhabitants.

One hundred and forty-seven deaths, or more than one-third of the mortality from all zymotic diseases last quarter, resulted from measles and its complications, which proved fatal in 122 instances during the preceding three months, and in 146 during the June quarter.

Ten deaths from small-pox and 1 from chicken-pox were registered last quarter.

The remaining deaths from zymotic diseases include 56 from fever, (13 typhus, 29 typhoid, and 14 simple continued fever), 35 from whooping-cough, 33 from scarlet fever—it is worthy of note that not one death from scarlet fever was recorded during the last five weeks of the quarter—13 from diphtheria, 38 from croup, 4 from quinsy, 6 from erysipelas, 32 from diarrhœa, 11 from dysentery, &c.

One hundred and seventy-three children died from convulsions; this number is 46 over the average for the corresponding quarter of the previous ten years.

Bronchitis caused 363 deaths, pneumonia 89, asthma 6, pleurisy 5, laryngitis 4, and lung disease unspecified 26; these 493 deaths, which are 112 over the average mortality from diseases of the respiratory organs in the fourth quarter of the ten years 1867-76, form 22 per cent. of the deaths from all causes.

One hundred deaths were attributed to heart disease, 11 to aneurism, 1 to pericarditis; 36 to apoplexy, 30 to paralysis, 13 to cephalitis, 9 to epilepsy, 4 to insanity, 24 to brain disease unspecified; 2 to jaundice, 1 to hepatitis, 32 to liver disease unspecified; 7 to Bright's disease, 2 each to diabetes and cystitis, 1 each to nephritis and stone in the bladder, and 15 to kidney disease unspecified.

Phthisis caused 217 deaths, or 10 per cent. of the total, mesenteric disease 38, hydrocephalus 50, scrofula 14, cancer 50, and gout 2.

Fifty deaths from accidents or negligence, 6 cases of homicide, and 5 of suicide were registered,

Officiers de Sante.

As our readers are aware, in France there is a lower grade in the profession who have certain powers limited in degree, and whom we may compare to a certain extent with our English unqualified assistants. Their position is a wrong one, as our unqualified assistants' *rôle* is a wrong one.

At the Academy of Medecine, Paris, Oct. 17th, M. Leven read a paper on "The Operations Interdicted to Officiers de Santé, and the Necessity of a New Law." The *Paris Médical* considers the question a very simple one. There is no half-sickness, consequently there should be no half-doctors. An Officier de Santé may be called to a woman in labour in the country, labour is retarded by some cause, which the forceps will specially remedy The Officier de Santé is not allowed to use the forceps.

A child may swallow a bean, the foreign body lodges in the larynx, and unless tracheotomy is performed the child must immediately die. The Officier de Santé cannot interfere.

Have we not had reason to say our unqualified assistant occupies a somewhat similar position. The French desire reform in their laws, and the suppression of two classes in the profession. We thoroughly agree with the necessity of the change suggested.

Our own grades might be altered with advantage, and we look forward to the time when there will be no longer any dispute as to whether the M.R.C.S. or the L.R.C.S. is the better diploma, whether the L.R.C.P.E., L.R.C.P. and L.K.Q.C.P.I. confer the title of Dr., and when the public will be able to send for the nearest doctor, knowing that they will be able to obtain the services of a practitioner who has been tested and found up to the standard. Individual ability will always command the field, for a diploma is not the *end*, but only the "beginning of the end.'

TWO CASES OF ARTERIAL PYÆMIA WITH COMMENTS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.,
Physician to St. Mary's Hospital.

Case I.—*Old Mitral Disease—Rheumatic Fever—Obscure Illness of Long Duration, Ultimately Distinct Signs of Embolism of Retinal, Cerebral, and Renal Arteries.*

Miss ——, æt. 25, seen January 9th, 1877. Has had rheumatic fever twelve years ago, with heart affection, was ill for many weeks. Lately has been attacked again in joints, but now the pain affects the head at the back part, not, however, continuously. The pain and stiffness were severe this morning, but have now quite gone off. Temp. 100; pulse weak. Hands hot. Urine very red and thick. Loud apex murmur heard at precordia, and in both backs. Second aortic sound weak. Bowels loose. Hyd. c cretâ, gr. ij.; pulv. Doveri, gr. ij., *h.n.* Mist. pot. citrat. efferv., ℥j.; pot. iod., gr. j., *quater die.* Chloral gr. xv., *o. n.*

13th.—Pulse 100, sharp; temp. 103. Sleeping better. Some rheumatism of right hand. Breathing better. Acidi. salicylici, gr. xv. sodæ carb., gr. xv.; tr. aurant, ℥ xv.; aq. ℥j., ad vices vi omni horâ *in dies.*

16th.—Temp. 101·8; pulse 108. No articular rheumatism. Skin moist. Speedy relief from salicylic acid, but after the second day it distressed her head, and was left off. To take four doses to day, and to-morrow to begin quinine in two-grain doses *ter die*, with effervescing saline *ter die* also.

26th.—Temp. 101; pulse 84. No articular rheumatism or lung mischief, but is very weak, and inclined to faint, has no appetite at all. Quinine exchanged for ferri. et quinæ citratis, gr. viij.; tr. nucis vomicæ, ℥ x; aq. ℥j., *ter die.*

Feb. 8th.—Temp. 101·4; pulse, 120. Tongue clean, moist. No sleep last night; had many crying fits and hysterics this morning; is now better. Has lately had twice three doses of salicylicate of soda, powdered quinæ disulph., gr. v. in solution, *ter vel quater die.* On this she improved at once, and began to eat, and continued better up to 17th or 18th, when she had a syncopic attack, and was found by her sister bathed in icy-cold sweat. I saw her on the 13th and on 20th. The temperature was normal both times, but the pulse was excited, about 100. The quinine caused some headache and deafness, and after the dose had been reduced, it was left off on the 19th.

27th.—Temp. 99·2; pulse 105. Lungs and heart as before. Low-spirited. Taking a small bottle of champagne daily. Calomel gr. i., *h.n.* Acidi nitrici, ℥ iij.; aq., ℥i., *ter die.*

March 6th.—Much better, more appetite. Temp. 100·2.

13th.—Worse. Temp. 104·7; pulse excited. No appetite. Is thirsty, languid, hardly speaks. Bowels right. Urine normal. Nights restless sometimes. One or two very suspicious spots on abdomen, but no pain in it. Lungs free. Murmur as before. Mixt. pot. citrat. ℥j.; c, ferri. et. quin. citrat. gr. viij., *ter die.*

15th.—Urine of natural colour, sp. gr., 1010, clear, slightly albuminous, neutral, or slightly alkaline.

16th.—Temp. last night, 104. Pulse to day, 105. Bowels right. Abdomen swells at night. No more spots.

20th.—Temp. on night of 17th was 105·8. In the mornings it has been about normal. To day, at 5 p.m., it was 101·2. Pulse 96. Bowels a good deal confined. No appetite. Face pale. No abdominal tenderness. Two rather doubtful spots. Spleen not notably enlarged. Forehead hot, had headaches. Nights restless. Gets up almost every day to her sofa. Hyd. c. cretâ, gr. ij.; aloes, gr. ij., in pill *h.n.* Acidi nitrici, ℥ ij.; aq. ℥j., *ter die.*

27th.—Temp. at 5 p.m. 98.4, pulse 100. Temp. at nights 100.4, in mornings 98.6. Is not so weak as she was. No fresh spots, bowels costive. Takes three pints of milk daily and beef-tea, but no solids except a little herring.

April 3rd.—Temp. to-day 102 at 4 p.m.; pulse 100

Some days appears much better, was so yesterday: ate ham and cucumber for supper, and was hysterical afterwards and slept badly. A few crepitations heard at posterior bases of lungs.

10th.—Temp. 104; pulse 93. On night of 8th temp. was 104, on night of 9th 102.2. Was very well until 8th, went out three times for a drive, then lost all appetite and got more thirsty, drinks six bottles of soda-water daily; nights bad since 8th.

17th.—Has had a great deal of rheumatic pain in various parts last four days, appetite very bad still, sleeping badly. No cough. Temp. 98.6 in mornings, and 100.4 at nights; is now, 5 p.m., 102.2; pulse 93. In both supra-spinal fossæ the breath sound is deficient, there is prolonged expiration, and some crepitations. Pot. chloratis, gr. x., *t. d.*

23rd.—In bed last four days with pains in joints and head; nights bad. Pulse 120, pretty full; temp. 101. Urine high coloured.

May 28th.—Temp. 101·4; pulse 115, of fair force. Lungs and heart as before. Has had a good deal of purpura lately; now there is but little to be seen. Skin is rough, with desquamating epidermis. Anæmic. Has had a good deal of rheumatism lately, for which she has been taking salicylic acid with advantage. I pressed a trial of change of air.

June 20th.—She went to Sydenham, where she was attacked with severe pain in left side, and was soon brought back. Her sight failed, and now it is doubtful whether she can see at all, though the eyes appear normal. The urine has become decidedly smoky and albuminous. Dulness in splenic region extensive, occupying the lower third of left side, as well as the posterior part of left hypochondrium. Dulness and deficient breathing in both lower backs; fairly good condition of upper fronts. Pulse 105; temperature 100. Rheumatic pain gone; is very pallid. I did not see her again, but she survived till July 16th. Dr. Griffith, who continued to watch her, has kindly informed me that she became totally blind, occasionally delirious, and hemiplegic, with intermittent attacks of vomiting and diarrhœa, and died in a typhoid comatose state.

CASE. II.—*Rheumatic Fever, Mitral Murmur, Obscure Fever of Typhoid character, Mental Impairment, Hemiplegia.—Post-Mortem Lesions of Mitral Valve and Endocardium of Auricle, Blocks in Spleen and Kidneys, Plug in Right Middle Cerebral Artery.*

A. W., female, æt. 17, admitted August 21st, 1877. She was suffering from rheumatic fever, her first attack, as was said; but there was a mitral systolic murmur. She was treated with salicylicate of soda, gr. xl., *o. h.*, ad vices vj., for several days, but with occasional intermissions.

29th.—Quinine was ordered, gr. v. *ter die*, with the salicylicate occasionally.

Sept. 6th.—She was free from rheumatism, took food well, felt comfortable, tongue was clean, she ate ordinary diet, had good nights. Some noisy râles were heard in backs on deep inspiration, breath sound was weak at right lower back.

10th.—Pulse was good, 104. She enjoyed her dinner (meat).

13th.—She seemed ill, but still took food well; tongue natural. Air entered the lungs well in deep inspiration, but the lower backs were dull, and no breath sound was heard unless a deep inspiration was taken, then crepitations and half moist râles were heard in plenty. Taking mist. salin., efferv. ℥j., *quartis horis*, last three days.

17th.—Much small petechial eruption of pin-point size in neck and trunk, this has been present for many days. Murmur at apex persists. Appetite not so good. Ammon. carb. gr. iv.; dec. cinch. ℥j., *ter die*. I was now absent from the hospital for two or three weeks, and have no notes of what passed in the interval, but there was no no material change.

Oct. 8th.—Pulse was 103, pretty regular. Tongue was coated and dry. She was taking glycerole of carbolic acid, ♏ x., *quartis horis*, and brandy 6 oz. since 4th.

12th.—Pulse 100, of good force, pretty firm. Tongue clean. Takes milk well. Has been in a perfectly typhoidal state for several days. Began to improve about two days ago. Is conscious, but looks very dazed and stupified.

15th.—Lost power over left arm yesterday; leg also affected.

22nd.—Hemiplegia continues. Complains of pain in head. Keeps patients in adjacent ward awake by screaming. She is rational when spoken to, but has the aspect of dulled or weakened intellect.

24th.—Cries out with pain in head; refers it to forehead. Manner foolish.

27th.—Is less noisy. Left leg moved better than left arm. Is conscious. Knows everyone; when a fresh nurse comes into ward soon gets to know her name. Is not at a loss for words.

30th.—Screams continually disturbing the whole ward. Chloral and morphia, and a free allowance of stout had not much effect in quieting her. She became very emaciated and demented, and was sent about Nov. 10th to the Marylebone Infirmary, where she died, Nov. 16th. The accompanying table shows that the temperature was notably higher during the earlier half of her illness, than during the later.

Table of Temperature in case of A. W.

The temperatures were not regularly recorded after this, but do not seem to have exceeded 102.

A *post-mortem* was made Nov. 19th. No sign of decomposition. Brain very pale, its convex surface showed no softening. On laying open the right Sylvian fissure the middle cerebral artery was found obstructed from about one-half an inch from its origin, and the three vessels into which it divided were also obstructed for about one-sixth of an inch. The plug in the large vessel consisted of a whitish material; that in the branches was of a rather darker colour. The convolutions of the island of Reil were softened, as well as the corpus striatum at its anterior intra-ventricular part, but no other part of the brain, which was normal. The heart presented some thickening and roughening of the larger flap of the mitral valve, and a very remarkable patch of vegetations, of villous appearance, on the endocardium lining the posterior part of the left auricle, adjoining the

attached mitral flap. Lungs and pleura normal. Spleen contained several good-sized, pale, whity-yellow fibrinous blocks; it was of large size, and adherent to the left lobe of liver. The left kidney contained a small fibrinous block; the right a large one, margined by a dark blackish zone of congestion. Liver and other organs normal. The blocks in the spleen felt very notably firmer and more substantial than the adjacent normal parenchyma; and on a sectional surface their level was evidently above that of the surrounding part. Microscopic examination of splenic blocks showed in most parts only the usual corpuscles, together with numerous yellow masses made up of disintegrated blood globules. In some spots there was much granular matter with fibrils like those of fibrine; and in others, from near the margin of the block, there was decided wasting of the natural structure, with masses of fatty molecules pretty numerously diffused among elastic fibres. In the blocks of the kidneys the tubes were very opaque, with coarsely granular epithelium. The Malpighian tufts also were opaque, their capillaries indistinct, as if overlaid by some granular film, and some of them also shrunken within their capsules. The bands of the matrix were also infiltrated with granular matter.

It seems to me very difficult to believe that the fibrinous blocks in this instance were formed simply in the way laid down by Cohnheim. If they had been at first mere masses of coagulated blood, they must, as they became decolourised, have undergone very considerable softening and wasting. I cannot see how they could remain so firm and prominent as I found them, if they were undergoing such changes as a cerebral clot undergoes while it is being gradually absorbed.

The chief interest of the above records consists in the demonstration they afford that febrile disorder, succeeding to rheumatic fever, may exist for a considerable time before any decided evidence can be detected of its real nature. In Case I. the pyæmic fever commenced about the end of January, but June was well advanced before decisive signs of its presence were manifested. In Case II. the interval was not so long, but still for about a month it was impossible to declare with certainty to what the persistent febrile condition was due. The occurrence of purpura in both cases preceded the advent of graver symptoms, and should be regarded in cases of valvular lesion as of ominous significance. It was an early symptom in Case II. The diagnosis, which was ultimately so fully justified in Case I., had been kept steadily in view as a probability from a very early period, but when the malady continued so obscure for such a long time it was difficult not to vacillate and imagine the existence of typhoid, or obscure remittent, or latent phthisis, or persistent rheumatism. The remarkable variations in the evening temperature exhibited in the table are, I think, more indicative of pyæmia than of any other febrile malady, and when present may aid the diagnosis. Thus, on August 25th the evening temp. was 103.6, on the 26th only 99.6. On September 4th the evening temp. was 98.4, while on the 3rd and 5th it was 104.6. On September 11th the evening temp. was 106, while on the 10th it was 102.4, and on the 12th 103.2. The absence of rigors in both these cases is noteworthy, and of course added to their obscurity. The absence of chorea in both these cases, when the blood must have long been contaminated with fibrinous detritus, should receive an explanation from those who uphold Kirke's doctrine.

THE Russian law as it now stands, compels a medical man to visit any one who sends for him, under penalty of a fine of from five to ten roubles for the first refusal, from ten to fifteen for the second, and from fifty to one hundred for the third. Moreover, any physician so offending, who may be in the service of the government, is liable to be dismissed. In 1869, a similar law was repealed in Prussia, and the profession in Russia is striving to obtain a similar concession.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,
Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page 64.*)

CASE X.—*Syphilitic Disease of Cerebral Vessels; Convolutional Degeneration of both Anterior Lobes, but more particularly of the Left. Marked Volitional Tremor, especially of the Labial Muscles. Progressive General Paralysis. Quasi-epileptic Seizures. Dementia.*

THIS case is one of that series which comes under the title of general paralysis of the insane. I have had twelve such under my care during the past four years; in seven of these there was a distinct syphilitic history, and in five absolute syphilitic manifestations. In none was there marked atheroma of vessels or increased arterial tension. These cases were all males between thirty and forty years of age. In five the paresis was coincident with mental derangement. In four the paresis existed before the memory was observed to fail, and in three mental alienation of a melancholic kind was noted previous to muscular inco-ordination. In five cases there was a large amount of albumen in the urine, and, what is interesting to note, each of these improved greatly under treatment, and in direct ratio as the albumen decreased. In all, the paralysis first affected the muscles of articulation and expression, especially the labial muscles. In seven there was decided epileptic seizure, with unconsciousness, and in five the epileptic seizures were not so pronounced, but simulated an intense state of sensorial hysteria, accompanied with deep emotional depression, and vocal manifestations (howling, barking, and groaning). In four cases the aura foreshadowing these seizures commenced in the tongue, as though innumerable pins were pricking it. In others it always commenced in the foot or hand of the side which was most paretic.

It will be found, if care be taken in diagnosis, that one-half of the body is invariably more paretic than the other. In ten out of the twelve cases recounted there was decided paresis of the *right* over the *left* half of the body. Only two were drunkards; the rest had been steady, well-conducted men, and all of them were really athletic in their young days.

J. D., æt. 33, came under my care on the 4th of October, 1876, and died on the 1st of October of the following year. He was a man of good *physique*, rather dark complexion, and quite free from any sign of premature degenerative change. Yet from mere facial expression alone it was conjectured that there was a weakness of intellect from cerebral disease, which became apparent immediately ideation and volition were called in action. There was a decided neurotic history in his family, but as far as he himself was concerned there was no evidence even of a neurosis until his present illness came on. He contracted syphilis at the age of 22, without experiencing any severe constitutional effects; he was married and the father of three children.

For some months previous to the paralysis his sexual desire was excessive, but actual virility was almost effete. Until he was twenty-eight years of age he was intelligent, industrious, even-tempered, and of a quiet amiable disposition, and was noted for his powers of physical endurance; he could walk twenty miles without feeling fatigued, and could throw a cricket-ball over 100 yards. The first indication of the approach of the disease was referable to the change in his moral nature; he became perverse and irritable, and decidedly emotional—as his wife said, the least thing would upset him; he would laugh and cry alternately from the slightest cause, and at these times the emotions would produce such a revulsion in the co-ordinating motor centres that the lips particularly, but his whole frame generally, became violently agitated. This instability of mind and its attributes preceded in

this case any other objective signs, but only for a very short period—so short, in fact, that I am inclined to doubt that any time really exists in general paralysis of the insane, where ideation and volition not only become co-incidently involved in the most incipient stage, but that the progressive degenerations are perfectly metrical and synchronous in their psychical and volitional manifestations.

He suffered from severe headaches, which were sometimes accompanied with vomiting, and always with constipation. When in this state he was depressed and inanimate; there was increased heat of head, with intolerance of light and migratory ptosis of both eyelids more marked in the left than in the right; the secretion of urine would be scanty, and the temperature, which was usually below the normal, would rise one or even two degrees.

Attacks like these occurred for the most part every three or four weeks. When he was at his best the temperature and secretory functions were normal. He first had a fit with unconsciousness in June, 1876, and a few months after this he came under my care in what might be called the second stage of the disease. There was defective reasoning power and want of voluntary muscular co-ordination; mere automatic movements were performed with some degree of exactness, and contrasted strongly with defective volition. When spoken to he usually said "yes" or "no," with a tremulous staccato articulation. This form of tremor in association with purposive idea-volitional speech is merely an exaggerated condition of the statement which has just been made relative to automatic and voluntary acts in general, and the following remark of the nurse was practical and explanatory. She said that he would go to her and speak a few sentences clearly and distinctly, and then the tremor of the lips commenced, but more particularly was this the case when she put a question to him for an answer. He then became confused, and his words were a mere jabbering. I have often noticed this with considerable interest. He could go through the letters of the alphabet and repeat a few words of one syllable with some degree of articulation, and so, in like manner, with the numerals until these became made up of more than one syllable, and then his difficulties increased with the number of syllables, so that where he had to make a combined effort to think and to speak the whole of the facial muscles were brought into the most inco-ordinate spasmodic action, which gave to the face a grotesque appearance; it almost amounted to an explosive action before the muscles had regained their original tranquillity. How very different is this from the ordinary speech ataxy and aphasia from localised brain lesions, as well as the imperfect articulation from disease of the pons varolii or of the bulbar nerves! Yet, upon a little reflection, it is quite easy to comprehend why the localisation of the function of articulate language presented a subject for so much discussion and difference of opinion amongst such learned men of the French school as Bouillaud, Velpeau, Gratiolet, Broca, and others, and we can now understand the reason why such differences ever existed, and explain them upon a psycho-physiological basis—thanks to the associated outcome of clinical and pathological work. In the *British Medical Journal* for June 19, 1875, will be found an article by Auguste Voisin, M.D. Medicin de la Salpêtrière à Paris, entitled "Analysis and Pathological Physiology of the Troubles of Speech in the General Paralysis of the Insane," explaining most clearly by pathological research how by certain lesions these various troubles are engendered. He says the troubles of speech in general paralysis are of various orders and bear different denominations. They are termed stuttering, drawling, hesitation, jabbering, stammering and quavering.

These denominations are too often confounded in the observations of general paralysis, and indifferently employed. The intimate cause of theses symptoms do not seem to me to be sufficiently known. I will here speak of the analysis and pathological physiology of the modifications of language. The faculty of language infers soundness (1) of the cortical substance of the anterior lobes of the brain—the seat of intellect; (2) of the nervous fibres, which pass from the cortical substance to the bulb, and which serve as conductors of the will; (3) of the bulb and the intra-bulbous nucleus of nerves animating the muscles, which are called into play during speech; (4) of the nerves animating the muscles; (5) of the muscles themselves.

The participation of these various organs is indispensable to the regular exercise of speech. It is not, indeed, enough for the movements of these muscles of tongue, pharynx, glottis, and face to be rightly co-ordinated; it is necessary to have a sound intellect, a knowledge and memory of words, and the voluntary excitement must be easily transmitted to the nerves proceeding from the medulla oblongata; every restraint on the action of the organs presiding over these functions will disturb speech. Upon the whole, patients suffering from general paralysis present troubles of speaking the etiology of which is multiple.

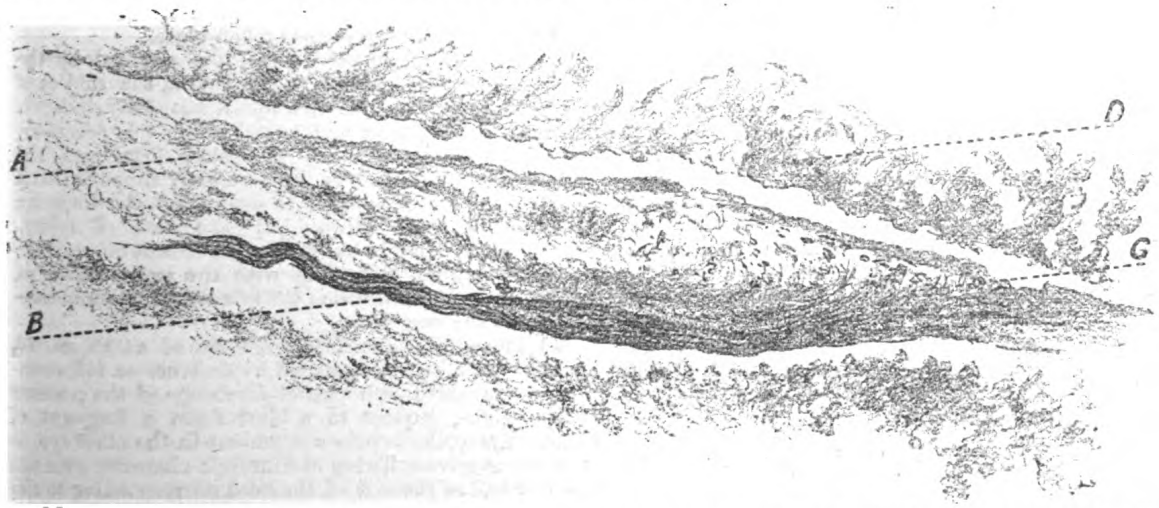
The causes of stuttering, of hesitation, of drawling, in speech originate in the brain because they are morbid phenomena, involving disturbance of the intellect of the will, and of the memory of words. The causes of jabbering, stammering and quavering in speaking have their origin in the medulla oblongata; they are symptoms corresponding with disturbance of automatic and involuntary co-ordination. The first order of the troubles of speaking is determined by the infiltration of the cortical substance of the frontal convolutions and of the island of Riel, with blastema, and the production of it by the production of embryoplastic nuclei—first in the vessels, next in the nervous substance, among fibres conducting the will, and by the ulterior organisation of these embryoplastic nuclei into fibrillary tissue. The second order of symptoms is occasioned by the infiltration of blastema and by the multiplication of embryoplastic nuclei in the vascular sheaths of the perivascular spaces; next amidst the nerve fibres of the bulb, and by necriobiotic alterations of the cells of the original nuclei of the nerves of the medulla, and especially of the facial. With this singularly interesting and truthful delineation of the pathology of the troubles of speech we will resume the thread of our clinical observations. We found that one of the chief features in the first and second stages of this disease in our patient was the want of voluntary co-ordinating power, and especially ideo-volitional co-ordinating power. There were no particular illusions or hallucinations, and his delusions were referable more to his personal physical strength than to anything else. He would often state that he could run or walk with any man in the ward, when he could scarcely get the length of twenty yards without stumbling.

It is interesting to note that, although the muscular development was good, and the electro-motor response was normal, yet the dynamographic manifestations showed that there was a marked inability on the part of the muscles to maintain their definite contractile power, and so, again, in raising weights. When lying upon his back he could raise forty pounds in weight with either leg. But this power was the engenderment of a primary molecular impulse, for upon second trial the legs would shake violently, and voluntary power was almost completely lost. This muscular fatigue is pathognomonic. The loss of reasoning power as the case progressed was in advance of the disturbance of normal motor acts, for it was only some three months before his death that he gave any objective evidence of failure of automatic power, and with this the general health began to decline, his appetite failed, he lost flesh rapidly, his mode of progression became more slow and purposeless, and the attacks of epilepsy became more frequent; his urine was sometimes retained, and at other times the sphincters were incompetent. He would commit acts of indecency towards the close of his existence, which were clearly indicative of his rapidly-failing mental powers. The urine was qualitatively but not quantitatively examined. It was usually

limpid, of a specific gravity varying from 1016 to 1020, always of an acid reaction, and free from albumen. It would appear from an article by Dr. J. Merson in the "West Riding Lunatic Asylum Medical Reports, 1874," entitled "The Urinology of General Paralysis," that there is an increase in the quantity of urea, and that the chlorides and phosphates are notably diminished. From the great labour which this paper must have given the author, and the care bestowed upon the examinations, I should think that the statements were exact, conclusive, and of the greatest practical value. Our patient, for a week previous to his death, was partially unconscious, and frequently convulsed, delirious, and excitable. There was a decided paresis of the right over the left half of the body.

At the *post-mortem* examination made twenty-four hours after death there was scarcely any cadaveric rigidity. The skull was of normal thickness and not adherent to the dura mater. This membrane was natural and the veins and sinuses were free from plugging. The arachnoid membrane was opaque throughout, and the sac was distended with fluid. The pia mater was rather anæmic than hypervascular. When the brain was removed it weighed 47 ounces, and gave evidence of softening. There was general convolutional flattening and thinning of the grey matter. This was especially seen to exist in the convolutions of the frontal lobes, but more particularly in those of the left hemisphere where they were shrunken and wrinkled, and it was evident that these lobes were especially and almost exceptionally the seats of disease. Upon section through the frontal convolutions, particularly the first and second, the grey matter was scarcely appreciable, and the white matter, in continuity was softened but free from hæmorrhagic staining. The brain substance of the centra ovale was pale but firm, and the other parts gave no evidence of any gross lesion.

The vessels were free from atheroma. Upon section they remained patulous, and their walls were thin, semi-translucent and hyaloid. I am indebted to my friend, Mr. W. H. Kesteven, for the microscopic examination of the brain and of the vessels. He found miliary and fuscous pigmentary degeneration throughout the nerve cells of the frontal convolutions which was more marked at the border line between the grey and white matter, but the pathological changes found in the vessels were of the greatest moment, inasmuch as they afforded a rational explanation of the vascular origin of the cerebral degeneration.



EXPLANATION. (*a*)

The woodcut shows a longitudinal section through a capillary vessel of the second left frontal convolution, where the coats are separated, and in some parts almost obliterated, by an aggregation of small cell or nuclear growths. This invasion will be seen to involve the inner rather than the outer tunics of the vessel, and this is the point upon which Heubner lays so much stress, and considers it to be especially diagnostic of the syphilitic origin of these changes. Upon further examination of other vessels these morbid products were to be seen in different stages of development and in their destructive effects upon the capillary walls. In some parts the lumen of the vessel was partially obliterated by the diffuse small cell growths proliferated from the normal epithelium of the lining membrane, whilst, in other parts, vessels were seen whose coats had been more or less destroyed by these adventitious products, and appeared to be made up nearly by a network of elastic and connective tissue fibres. I have detailed this case with observations at some length because in its consideration are embodied several questions of considerable pathological and psychological importance. For instance — What class of mental troubles can we ascribe, either directly or indirectly to syphilis as its cause? I should say that syphilis, by the diffuse changes which it is known to instigate in the small vessels of the brain, was the cause of at least two-thirds of the general paralysis leading to dementia, as we meet with it in this country, and next to this we can include melancholia, which is, however, as far as my own observation serves, more due to the degenerative changes resulting from alcohol than from syphilis. Lastly, Are we in a position to maintain this doctrine of Dr. Heubner in respect to these vascular changes being the result of syphilitic influence? It certainly seems to carry with it considerable weight, but as yet it has not been sufficiently investigated by pathologists in this country, although there can be no question concerning its value. Dr. Heubner points out that this syphilitic degeneration differs essentially from atheromatous degeneration in its duration, anatomical appearances, and mode of termination. He says that whilst atheroma attacks the greater and middle arteries, syphilis attacks the middle and smaller ones; that whilst atheroma attacks any or all of the arteries of the body, syphilis attacks only the smaller vessels of the brain. For my own part, I am not at all inclined to agree with those observers who speak of syphilitic disease of the main arterial trunks. There is little doubt but the chief factors here are the poisons of alcohol, gout, and rheumatism, or of these combined, but not of syphilis. Therefore, if we have well marked degenerative changes in the small vessels of the brain, which differ from atheroma on the one hand, and from the hypertrophy and connective tissue changes of Bright's disease on the other, we may (and especially with a syphilitic history to guide us) come to a fairly rational conclusion that they are essentially the outcome of syphilis.

(*a*) Since this paper was written some well-executed drawings have appeared, showing this syphilitic change in the cerebral vessels, by Dr. Barlow, Dr. Gowers, Dr. Greenfield, and Dr. Davidson in the "Pathological Society's Transactions" for 1877.

WE are glad to notice that the mortality of Dublin last week was reduced to the proportions of London and Edinburgh, namely, 28 per 1,000. Dublin has not shown so favourable a rate for many weeks; we hope it will be maintained, as our repeated protests against the laxity of the city authorities had no other object in view.

Clinical Records.

LIVERPOOL SOUTH DISPENSARY.

Ulcer of Duodenum found immediately after Birth.

Under the care of CHAS. ROLLESTON WOODS, A.B., M.B. Dub.

A CHILD, a few hours old, was brought in suffering from hæmatemesis, which had continued from birth without intermission. As no cause could be ascertained astringents were given, which stopped the hæmatemesis for a time, but soon after it recurred, accompanied by melæna, and the child died thirty-five hours after birth. At the *post-mortem* examination I found the lower lobe of the right lung completely hepatised. The rest of the lungs were healthy. In the abdominal region I found extensive peritonitis, and on opening the duodenum there appeared on the posterior wall a circular ulcer about one centimetre in diameter, with defined edges, and extending through muscular and mucous coats, and perforating the serous coat by one or two very small openings. Both the parents are healthy, and, according to their own statements, never had syphilis, which, if true, is not a little remarkable.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY, Surgeon to the Hospital.

(1.) *Excision of Knee-Joint.*—(2.) *Ditto of Wrist, with portions of the Ulna and Metacarpal Bones.*—(3.) *Amputation of Thigh.*—(4.) *Ditto above Ankle* [*Syme*]. (5.) *Depressed Fracture Skull. Trephining.*—(6.) *Refracture of Leg for deformed union.*—(7.) *Enucleation of Eye.*—(8.) *Two Cases of Cancer Lip.*—(9.) *Circumcision.*—(10.) *Amputation of Supernumary Great Toe.*—(11.) *Ditto of Finger.*—(12.) *Club Foot; Tenotomy.*—(13.) *Anchylosis of Elbow.*—(14.) *Dislocation backwards both bones of Elbow.*—(15.) *Compound and comminuted fracture of Forearm.*—(16.) *Severely crushed Hand from machinery.*—(17.) *Autopsy on a case formerly treated for Ilio-Femoral Aneurism.*

THE first six of the cases quoted in above heading have already been referred to in previous issues of this journal (*a*), but it is thought desirable, now that they have concluded, to give their termination. They, and the other patients, the subjects of the present summary, were amongst the "discharges" during the last six weeks of the year just ended.

(1.) In the excision of knee case, convalescence, whilst advancing with exceptional rapidity, was interrupted and delayed by a severe attack of erysipelas, which being recovered from, improvement again progressed, the young woman returning to her home in England just four months after the operation, able to walk with comfort, and, so great had been the accommodation of the pelvis and lower spine, without any high heel or sole. In connection with the attack of erysipelas, it may be noted that hers was the only case which presented in the hospital about the time; there had been no example of the affection "in the house" for a considerable period previously, and though there happened, when this one occurred, to be quite an exceptional number of heavy operation and severe injury cases in the large ward in which the girl lay, no other patient took it.

(2.) Concerning the wrist resection, quite as favourable a report cannot yet be recorded, though the lad left the hospital with a fair enough prospect of eventually having a useful limb. The sinuses had all healed, and the site of the excised carpus and adjoining bones became filled with a firm fibrous material, leaving a not unshapely hand. There was some and increasing power of control over the fingers.

(3.) The thigh amputation was on a stout female, æt. 25, for long-standing disease of knee and lower end of femur. Resection was attempted, but the femur proved to be implicated so high as to necessitate section about mid-thigh, and the operation being converted into an amputation by long anterior rectangular flap method. Though the woman's health appeared excellent all through, recovery was slow, the stump not being entirely healed for some ten weeks. (*b*) The bone specimen on boiling exhibited to a remarkable degree the characters of lightness and friability.

(4.) The "Syme" amputation was for long-standing and extensive caries in a woman, æt. 30, who made a splendid recovery, being able to leave the hospital in less than two months with a soundly-healed and perfect stump, on the heel flap of which she could readily bear her weight, and, using a high-heeled boot apparatus, walk, without the aid of a cane even, in a manner that showed how the limb would, after a little practice, be quite equal in point of utility to its fellow.

(5.) The girl, the subject of trephining for depressed fracture of skull, with escape of brain matter, continued to amend steadily; the paralysis noted as existing in the right upper extremity entirely disappeared, and when she was discharged from the hospital five weeks after the operation, perfect recovery had taken place.

(6.) Circumstances necessitated the removal by the mother from the hospital of the infant, the subject of refracture of leg, ere yet the result was fully declared. Though three months had passed since the operation, consolidation was still not absolutely firm, and the little limb continued to be kept steadily supported on a light posterior gutter-splint, to counteract the lingering tendency to bend forward at the seat of injury. Doubtless the delay in union was dependant on constitutional depravation coincident with the severe attack of whooping-cough with which the infant had sickened subsequent to the operation.

(7.) The enucleation of the right eye of a man, æt. 74, a stone cutter, was necessitated by destructive inflammation, accompanied with partial discharge of the contents of the globe, sequent to a blow from a fragment of stone. Sympathetic pain was present in the other eye, as well as excessive suffering of neuralgic character over the anterior half of the side of the head corresponding to the injured eye. This condition was completely relieved by the enucleation, the patient leaving the hospital in good health a little more than a fortnight after it. The isolation of the globe on this occasion was a matter of considerable difficulty owing to intimate adhesions of a firm fibrous character, which existed over its entire posterior surface; these were so dense that part of the structure had to be removed with the damaged eye.

(8.) Of the two cancer lips, one of exceptional dimensions was operated on purely for palliative effect and at the urgent solicitation of the patient, a labourer, æt. 51. This was a case of cancerous infiltration, irregularly involving the entire lower lip, nowhere for less than an inch of its depth; the disease extended beyond both angles of the mouth, the morbid growth on the left side being prolonged far up into the cheek beneath the integument, engaging the mucous membrane extensively, but not implicating the skin much further than the angle of the mouth. The removal of the disease entailed the cutting away of a very large mass. After securing a number of vessels, the tissues covering the chin were widely detached by means of a Langenbeck's curved sharp-edged rasparatory, which, with some further dissection into the neck, and of the cheeks on either side, furnished a very fair new mouth; the whole, when brought together and retained in position by hare-lip and entomology-pins, showing wonderfully little deformity. Reactionary hæmorrhage necessitated the re-opening of the wound a few hours after

(*a*) Those of 26th of September, 21st and 28th November, 1877.

(*a*) There was subsequently exfoliation of a small scale of bone.

the operation. Subsequently, the case did well, and the man left the hospital in a month, presenting a marvellously good appearance, and expressing himself deeply gratified at the amount of palliation obtained for his wretchedness.

In the second case of cancer-lip the disease was of very limited extent, and entirely confined to the free border. It was easily removed by small elliptical incisions; the little wound had entirely healed in three days.

Amongst other cases of minor operative surgery was a circumcision and amputation of supernumerary great toe, which each possessed points of interest; there was also a disarticulation of finger and tenotomy for club-foot.

(9.) The circumcision was on a man, æt. 30, the subject of acquired phymosis. The orifice, through which the urine was discharged, was the merest pin-hole, scarcely discernible to sight on the closest inspection—through it a fine pocket probe could not be introduced, yet the man had borne with this condition for many years. The foreskin was removed by Ricord's operation; the mucous lining proved to be exceptionally tense, thick, and leathery—its cut edge was accurately co-apted to that of the integument, and united by several points of carbolised cat-gut suture. The wound healed entirely in four days.

(10.) The supernumerary great toe was removed from a young woman: it was as large as the natural one, similar to it in appearance, but standing out from the foot at right angles; pointing directly inwards it effectually prevented the wearing of any foot gear. The articulation at its proximal phalanx seemed to be a portion of a joint common to it, and the meta-tarso-phalangeal articulation of the normal great toe—wherefore, instead of practising disarticulation, the phalanx was cut with the forceps, so as to keep clear of this joint. The little wound healed kindly, and without deformity. The girl had also double great toe on the other (left) foot. Here, however, the toes were of smaller size, ran parallel to one another, being in part fixed together, and did not materially interfere with a boot being worn.

(11.) The finger case occurred from neglected paronychia of the third finger of the right hand in a pensioner, æt. 60, resulting in extensive disorganisation of the soft parts, and necrosis of all the phalanges. The digit was removed at the metacarpo-phalangeal articulation—the wound healed moderately quickly by granulation.

(12.) The club-foot was in a female infant, of 11 months, who had exaggerated talipes equinus. With division of the tendo-Achillis and bandaging to a suitable splint, the case did well.

Two cases of damaged elbow required manipulative interference.

(13.) In one, a stout, large woman, æt. 26, had fallen heavily some weeks previously, on the right elbow, and seemed to have received fracture of the internal condyle, this being followed by consecutive fibrous anchylosis of the joint. The adhesions were freely ruptured, under chloroform, and considerable power of motion regained.

(14.) In the other, a very stout and powerful young man fell down a staircase, rather better than a week prior to coming under observation. The parts were then so enormously tense and swollen that accurate diagnosis was out of the question. Under the constant application of cold, the swelling became somewhat lessened, and the presence of displacement was recognised. Chloroform was given and a dislocation of both bones backward reduced, but owing to the great size of the parts, not without considerable difficulty; speedy amendment of the local trouble followed.

There were two other interesting cases of recent injury of the upper extremity of so severe a character as to necessitate indoor treatment. In one—

(15.) A man, æt. 23, fell about 20 feet out of a window; in addition to severe contusions about the pelvis and trunk, there was a compound fracture of the right ulna about three inches below the elbow; the radius on the same side was also extensively comminuted above the wrist. The wound having been "sealed" with lint soaked in the blood, and over it a compress of lint saturated in Friar's balsam, the limb was put up on anterior and posterior splints. The wound healed in a few days, and the case progressed most favourably, speedy union occurring with early and good use of the limb. In the other case:—

(16.) A lad, æt. 14, had his left hand caught between rollers; the subsequent effusion and tension was so great that when the boy came into the hospital the hand was almost globular in form, both palmar and posterior surfaces being gangrenous. The sloughs large and deep took several days to separate, after which the parts began to heal rapidly, and notwithstanding the extensive destruction and loss of soft parts, there seemed at the time of the boy's discharge from hospital fair promise of an unimpaired limb being preserved. It could not be ascertained whether any of the metacarpal bones were broken or not.

(17.) An opportunity was afforded of making a partial autopsy on a man who had formerly been treated for an ilio-femoral aneurism of considerable size, and which had consolidated. The case was at the time briefly referred to in the issue of this journal for the 25th of July last year. On Christmas Day, the patient applied at the hospital again, in a state of extreme prostration from a fresh graft of aggravated capillary bronchitis. The weather was, and had been for some days previously, exceptionally hard and severe. The man made no attempt at rally, and only lived two days, the tissues over the old aneurism were found condensed, hardened and thickened, the artery for some inches being a firm rope-like structure about as large as a No. 18 catheter, its channel completely obliterated, from the origin of the deep epigastric and circumflex vessels downwards to a bifurcation corresponding to the point of origin of the profunda.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At the ordinary meeting of this Society, held on the 22nd inst., Dr. C. West, President, in the Chair, Mr. C. Higgins read a paper on a case of "Rodent Ulcer." The patient was a married woman, æt. 45. Her health had always been good. The disease commenced thirteen years before admission to Guy's Hospital, at the remarkably early age of thirty-two, as a pimple on the left side of the nose, which, however, showed but little tendency to ulcerate until five years after its first appearance. During the progress of ulceration a second pimple, of apparently the same nature as the first, made its appearance in the angle between the right side of the nose and cheek; it did not, however, ulcerate. The eyeball, which was quite healthy, was excised, and the ulcerated surface destroyed with a paste of chloride of zinc and starch applied on strips of lint; after separation of sloughs some cicatrisation took place. The disease soon commenced again, and eighteen months later the surface of the ulcer and adjoining infiltrated tissue were destroyed with the galvanic cautery and chloride of zinc paste; the second pimple was also burnt out. After separation of slough, cicatrisation again took place, but four months later the disease was again spreading rapidly. The whole of the thickened margin and base of the ulcer, with a large amount of the adjoining healthy structures were cut away with a scalpel, the bleeding stopped with a "thermo-cautery," and chloride of zinc paste applied all over the cavity left. The wound finally healed entirely, but subsequently some recurrence took place, and the diseased tissues were again removed with knife, cautery, and caustic. Cicatrisation once more took place, and the wound has since remained firmly healed.—Mr. Gaskoin introduced a male patient, æt. 57, who had apparently a rodent ulcer on the left side of the vertex.—Mr. Hulke showed some of the late Mr. Moore's preparations of this disease from the museum of the Middlesex Hospital. Mr. Moore was the first who attacked some of these advanced cases of rodent ulcer. Mr. Hulke also showed photographs of some of his own cases, and one of Mr. G. Lawson's. In all, the method adopted was free

excision with the knife, the actual cautery close to the bone, and the free application of the chloride of zinc paste. Unless these cases were dealt with sweepingly at first, the disease may be excited to increased activity. The ulcer in Mr. Gaskoin's case had not the character of rodent cancer, and its situation in the hairy scalp was extremely rare.—Mr. NETTLESHIP was under the impression that rodent ulcer almost always began as a pimple.—Mr. BARWELL agreed with Mr. Hulke that "cancer" was a better term than "ulcer" for this disease. The distinction between such cases and simple lupus, which could be cured by simple scarification, seemed great. Mr. Barwell added that he now used Paquelin's thermo-cautery in the place of the galvano-cautery, and by its means had recently eradicated a rodent ulcer of the face.—Mr. HULKE remarked that rodent cancer is epidermal from its very origin, and never begins beneath the skin.

A paper was then read "On the Proportions of Red Corpuscles in the Blood in some Skin Diseases," by GEORGE THIN, M.D. The investigations recorded in this paper were made by the methods introduced by M. Malassez, of Paris, which consists of diluting the blood to a known degree by artificial serum, and in counting the number of corpuscles contained in a given quantity of the diluted blood. The latter part of the operation is done by counting the corpuscles seen in a measured length of a capillary tube of known capacity. M. Malassez has found that in Paris the number of red corpuscles in a millimetre cube of blood varies in healthy men between four and five millions; in females the number is less. The same observer found that the number diminishes greatly in wasting diseases. In cancer he counted in a man as low a number as two millions and a-half, and in a woman one million and a-half. In phthisis his lowest numbers were, in a male two millions and a-half, and in a female slightly under one million. In selecting persons suffering from skin disease for examination, only those were chosen in whom there was no reason to believe that the condition of the blood was affected by medicinal treatment, or the existence of other maladies. The following numbers were found in cases of skin disease:—

Psoriasis: man, aged 25 ...	5,250,000	per mm. cube.
,, ,, ,, 25 ...	4,820,000	,,
,, woman, aged 27 ...	4,330,000	,,
,, ,, aged 18 ...	4,448,000	,,
Eczema: man, aged 60 ...	3,750,000	,,
,, ,, aged 19 ...	4,200,000	,,
,, girl, aged 12	4,420,000	,,
,, woman, aged 26 ...	4,350,000	,,
,, ,, aged 20 ...	3,880,000	,,
,, ,, aged 25 ...	5,050,000	,,
Pemphigus (chronic): man, aged 30—40	3,580,000	,,
Acne sebacea: girl, aged 16 ...	4,050,000	,,
Prurigo (Hebra): boy, aged 13	3,420,000	,,
(Counted in same case after an interval of a month ...	3,550,000	,,
Acne rosacea (second stage): man, aged 47	4,140,000	,,

Now, in examining the above table it will be seen that the state of the blood as regards the quantity of its red corpuscles differs in skin diseases very little from that which obtains in healthy individuals. It is seen, also, from these figures that an outbreak of psoriasis is compatible with a high proportion of blood corpuscles. In eczema the number is about normal. The case of the man aged 60 was a severe one, and had lasted many months, and the hygienic conditions were bad. In the man aged 19 the disease had invaded in a scaly infiltrated form nearly the whole surface of the body, and had lasted for a number of years, the case being one of great severity. That in such a case the number should have exceeded four millions—the enumeration having been repeated several times with great care—shows that a diminution in the number of red corpuscles is not a necessary condition of eczema.—Mr. GASKOIN pointed out that the old treatment of psoriasis by venesection was rather borne out by these observations, which showed an increase in the blood corpuscles in this affection.—Mr. M. BAKER understood Dr. Thin to say that these observations disproved the dependence of certain skin diseases upon morbid blood-condition. But there were no doubt other conditions besides the proportion of corpuscles to be taken into account.—Dr. THIN only meant to convey that it was too much the fashion to assume a profound blood condition in diseases of the skin without any grounds for the assumption, and his observation only showed that in one respect at least the blood was not modified

A paper was also read by Dr. JOHN HARLEY in continuation of a former paper on "Simple Atrophic Sclerema."

MEDICAL SOCIETY OF DUBLIN.

THE third meeting of the Session was held on Wednesday, January 2, Dr. GORDON, President in the chair.

Dr. WALTER SMITH read a paper on

FACIAL PARALYSIS, WITH REMARKS ON THE ACTION OF INDUCED CURRENTS AND INTERRUPTED VOLTAIC CURRENTS.

After narrating briefly the notes of several cases he discussed the question of the differential action of induced currents and interrupted voltaic currents in its bearing on the diagnosis and prognosis, especially of peripheral paralysis. Speaking of the curious difference in action of a slowly and a rapidly interrupted galvanic current upon paralysed muscles, he expressed the opinion that the cause lies not only in the abbreviated duration of the current, but also in the extremely short interval between the successive shocks of a rapidly interrupted current, the paralysed muscles being exhausted by a too rapid succession of stimuli. The paper was illustrated by several diagrams.

The PRESIDENT said he had seldom listened to a more practical paper at any meeting of the Society than that just read by Dr. Walter Smith, both for diagnosis, prognosis, and practical treatment. They certainly met with cases where the disease was of a transient character, and also cases commencing with peripheral paralysis, and then going on to brain disease.

Dr. HENRY KENNEDY rose to bear testimony to the value of the admirable paper just read. He desired to mention one remedy which he had known used with success after even electricity had failed but at a time when electricity was not used in that form, and with that accuracy and detail to which reference had been made in Dr. Walter Smith's communication. The remedy he (Dr. Kennedy) referred to was mercury. He recollected one case in which the late Sir Philip Crampton had recommended the use of mercury, and had pushed it even to salivation and with success. He (Dr. Kennedy) was sure any patient would be willing to submit to even that cure rather than continue to endure the affection. Even in what seemed to be the most incurable cases it had been used with benefit. The transient character of the affection had repeatedly come under his notice. It was by no means an uncommon thing to see the affection confined to one side of the face, and it was of so transient a nature that even within a few hours, without doing anything for it, it passed away. It was, he believed, more or less in connection with the circulation. In reference to peripheral paralysis, he would venture to remind the Society of the admirable remarks of the late Dr. Graves on the subject. But it was not in reference to the face that he spoke, but in reference to the extremities. The application of cold to the feet and legs was quite capable of itself of producing paralysis.

Dr. AQUILLA SMITH.—Did you ever see more than one case of that disease treated successfully with mercury?

Dr. KENNEDY.—Never; but electricity was not then so well applied as it is now.

Dr. AQUILLA SMITH had treated about half-a-dozen cases of this kind with mercury, but it signally failed, and he treated those cases subsequently with success by electricity, and all he used was the common electro-magnetic machine—the small American machine.

Mr. H. G. CROLY said that the last case described in the paper of Dr. Walter Smith came first under his (Mr. Croly's) observation, and the child who got the attack of facial paralysis was perfectly well in the morning, and a few hours after taking some violent exercise facial paralysis came on, and the case was a most characteristic one. He applied leeches to the stylo-mastoid foramen, and a couple behind the ear, and that gave relief for a time. Then he applied a blister over the back of the nerve, and afterwards he gave small doses of iodide of potassium and painted the nerve with iodine. Later again, he used electricity, and in its application she suffered a good deal of pain; perhaps the latter was caused by his not having applied it so satisfactorily as Dr. Smith afterwards did, for on questioning the child, she said that when Dr. Smith administered the electricity it did not hurt her at all. He might observe that he felt a small gland in the region of the stylo-mastoid foramen, and whether that gland (which was in the track of the nerve and which was about the size of a

small pea), had anything to say to pressing on the nerve, or whether it came on from the irritation of the blister, it would be difficult to say. That case was almost well now, though there was a slight deformity still existing. The patient could shut her eye, whistle, and wrinkle her brow, but there was still a slight appearance of paralysis remaining. He thought in that case that the delay between the early treatment of leeching, &c., and the proper application of electricity was too long, and he thought the cure had been delayed a good deal on that account, and he thought there was a good deal of muscular atrophy allowed to go on. He had no doubt that had the electricity been sooner applied by Dr. Smith with the great care he afterwards used in its administration, the case would have been well by this time. He might mention, too, what he might call surgical cases of paralysis. Recently he removed a tumour from the parotid region, region, and the day after the operation the patient had all the symptoms of facial palsy. He saw the patient within a very short time, and he had recovered the use ol the muscles of the face, so that one would scarcely know that there was a trace of facial palsy remaining. He had another case where facial palsy followed the removal of one of the jaws, and in that case the face recovered itself completely. There was another case which he thought worth mentioning. Two years ago a lady came to him from the co. Limerick, and he was consulted about her. She suffered great pain at the side of the head and ear. Immediately on looking at her he observed that she had lost the power of the orbicularis muscle : she had complete paralysis of that muscle—facial palsy, in fact. He suggested a consultation with an aurist, and when that took place they immediately came to the conclusion that the case was a very serious one, and he gave an unfavourable opinion of its result. The lady died shortly afterward with head symptoms, convulsions, &c. There was complete deafness in that case. He would like to ask Dr. Smith whether he had any experience of the injecting of minute doses of strychnine in cases of facial palsy?

Dr. FINNY said the question of the interval between the occurrence of facial palsy and the application of either faradic or galvanic electricity was a very important one. At present he had a case of the kind in which he was employing electricity. In that case the faradic excitability was greatly diminished, but not entirely lost. Even with a strong current the muscles did not respond in the least, but with galvanic electricity there was diminished excitability. He had hoped that Dr. Walter Smith would have been able to throw more light on the question of prognosis than he had, because his cases left one very much in doubt as to whether even in spite of the action of galvanic excitability the disease was accelerated or diminished, and whether the causes would be repeated or not.

Dr. WALTER SMITH in reply, said that as to the action of strychnia administered hypodermically, he had tried it in several cases of facial paralysis, and he had never found the slightest improvement result from its use. With regard to what Dr. Finney had said, all he would say was that the sooner electrical treatment was begun and carefully carried on, the better for the patient, and as regarded prognosis, that could not be given from a single examination, or from any particular day of the case. It must be the result of several examinations made within short intervals of each other.

Dr. J. W. MOORE then communicated a report of a fatal case of typhus with hyperpyrexia.

The Society then adjourned.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
AND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER VIII.—TREATMENT : PRESERVATIVE.—
(Continued.)

Caustics.

Lipscomb preferred the use of a caustic when it could be immediately and accurately employed, and we have mentioned Youatt's belief in the nitrate of silver, which seems to have been also recommended as a local application by a German professor, M. de Mederer. (*a*) The caustics which have been and may be employed are numerous, and may be more or less lauded. The strong fluid acids, as acetic, nitric, sulphuric, hydrochloric, and carbolic acid, and such powerful escharotics as nitrate of silver, perchloride of iron, muriate of antimony, and corrosive sublimate, have been generally employed, as well as strong ammonia, caustic potass, or soda, chloride o zinc, quick-lime. That agent must be employed, which is most convenient and most prompt, time being an all-important consideration.

Whether a solid or fluid caustic be used, it should be employed unsparingly, and some of the best are nitrate of silver, potassa fusa, muriate of antimony, perchloride of iron, or carbolic acid.

The fluid caustics have been more resorted to, as they most certainly penetrate all the sinuosities of the wound. The nitrate of silver is generally at hand, as most surgeons carry it in their pocket-cases. We need not enter into detailed particulars as to the exact methods of procedure in each case, as they are simple ; their efficacy, however, depends on their free use.

The Result of Cauterisation, Excision, and Caustics.

It is to be regretted that we have not more means of ascertaining to what extent cauterisation, excision, and the application of caustics to wounds have been used, nor of estimating their relative value ; we have some isolated and individual statistics, as those of Blaine, Youatt, Earle, Ekstrom, Wendt, and from Zurich, and they are of a sufficiently satisfactory character, establishing the advantages of precautionary measures.

We are indebted to Fleming for the following particulars :

M. Bouley, impressed with the great interest that belongs to this question, has endeavoured to make the most of the statistics available to him, and has given the result in the following terms :—"If we compare with regard to their consequences the bites from rabid animals, which have been cauterised and those which have not, a considerable difference is remarked with regard to their consecutive innocousness. In fact, in 134 cauterised wounds, the innocuity is shown in 92 cases, and the mortality in 42 ; or 68 per cent. in the first, and 31 in the second. For the non-cauterised wounds the result is the reverse of the above, and is much more manifest. In 66 of these the mortality is 96, or 84 per cent., and the immunity only 10 or 15 per cent."

But this excellent authority adds, in default of sufficient information with regard to the cauterised wounds, it has not been possible to establish a distinction between them as to the degree of cauterisation they received or the time at which it was applied—two conditions on which the certain efficacy or complete inutility of this means of preservation depend. If this information had been furnished, there is every reason for stating that the number of cauterised wounds which remained inoffensive would have been considerably increased, as the destruction by fire of the tissues in contact with, and even impregnated, by the virulent saliva, it may safely be asserted, prevents the disease, if resorted to before absorption has taken place. Of 115 cases of hydrophobia terminating in death in France, Tardieu has tabulated them as follows, in order to show the results of neglect or tardy cauterisation of the wounds :—

Years.	Died of Hydrophobia.	Not Cauterised.	Tardy Cauterisation.	Insufficient. Cauterisation.
1852-53-54	44	26	18	0
1855	21	11	5	5
1856	20	11	6	3
1857	13	10	3	0
1858	17	6	5	6
	115	64	37	14

In Algeria, out of the 16 cases of immunity already referred to, 14 had the wounds inflicted by rabid animals cauterised more or less promptly ; in two instances three persons were cauterised 24 hours after being wounded, and a fourth in 36 hours. The following table gives the detail of the 16 cases :—

(*a*) "Medical Facts and Observations," vol. i., p. 17.

Immunity after—

Immediate cauterisation with the hot iron	7
,, ,, by cones of gunpowder ...	1
Cauterisation by late application of hot iron	1
,, after at least 24 hours	3
,, ,, ,, 36 ,, ...	1
,, with muriate of antimony after 3 hours	1
Immunity without adopting precautions	2

Thus it will be seen that one half of the cases of immunity might be supposed to be due to immediate cauterisation, three-eighths to tardy cauterisation, and one-eighth escaped without any treatment.

Of the 47 deaths tabulated by Roucher as occurring in Algeria, we find that their relations with preventive or preservative measures are as follows :—

Died without wounds having been cauterised	25
,, ,, indications of precautions	10
Died after tardy and incomplete cauterisation with hot iron	2
Died after tardy cauterisation with the hot iron ...	5
Died after tardy and incomplete cauterisation with nitrate of silver	1
Died after immediate cauterisation with ammonia, supplemented by the hot iron an hour and a-half subsequently	1
Died after immediate cauterisation with ammonia ...	2
,, ,, ,, ,, ,, hot iron ...	1

In 47 deaths only one occurred after immediate cauterisation with the hot iron ; 12 were preceded by delayed or insufficient cauterisation, and 35 had not been submitted to any preventive treatment, for it is very probable that in the 10 cases which afford no indication of precautions having been adopted, none were resorted to, so that, of the 37 cases allowed to take their natural course there were 2 of immunity and 35 deaths, or a mortality of 94·6 per cent. Of the 9 in which cauterisation with the hot iron was immediately employed there was only 1 fatal case, or a mortality of 11 per cent., and of the 16 cauterised after some delay, or in a manner more or less imperfect, there were 10 deaths, or a mortality of 62·5.

Among the fatal cases more or less known there was only one in which the wounds had been at once treated with the actual cautery, and another in which ammonia was applied first and the hot iron afterwards. In three instances there was a delay of nine and twelve hours, and in other three, of some hours. In three more of the 47 cases cauterisation was incompletely effected by ammonia or nitrate of silver ; in one case cauterisation was only resorted to after two days, and twice the wounds were dressed immediately with liquid ammonia.

The only patient who died after having his wound immediately cauterised with the hot iron was believed to have been saved, as he enjoyed excellent health for six and a-half months, and in that time had taken part in the expeditions against the Kabyles in 1851, and returned quite well.

In the two which had the wounds dressed immediately with liquid ammonia the period of incubation extended to 116 days and 130, a circumstance which might give rise to the supposition that caustics have a retarding influence on the development of the disease.

General Treatment.

Having thus complied with some of those measures recommended by the test of practical experience, the physician may have to exercise his discretion in further dealing with his patient, and it may become a question whether he should order any medicine or any supplementary treatment. Though we are satisfied that there is no *specific* internal remedy, yet the administration of some form of medicine may have a beneficial action in soothing the fears of nervous or timid subjects. Mental influences play a very important part in this disease, and they must necessarily not be overlooked. The physician will be guided by the temperament and peculiarities of his patient, and if he considers the administration of calomel, sulphite of soda, magnesia, or carbolic acid likely to satisfy his patient's mind, he should certainly order such innocent medicaments. Bouley says : He is convinced that the practices or medications, whatever they may be, which addressed themselves to the *morale* of those who are the victims of rabaic inoculations may prove very useful, and that he has caused persons who were labouring under the dread of hydrophobia to take some innocent beverage as an infallible specific. He adds : "The memories I entertain of the immense contentment it has produced have always confirmed me in the belief that it is not good to destroy such illusions and belief, but, on the contrary, to create them."

This no doubt may be called charlatanism, but when we remember that in a large number of diseases we are obliged to order some innocent form of medicine in order to secure the adoption of the rules of diet and hygiene, which are our real remedial measures ; it may be more excusable to order a placebo when we are dealing with patients who are harassed by anguish and phantoms of the mind, and who require to a greater degree all the encouragement and consolation we can lend. We must act on the mind by our own moral power and influence, and by impressing, if remedial measures are adopted, their security. If our patient's nervous system requires stimulation we must adopt appropriate treatment to restore it to its normal tone. If sleep is absent or disturbed, we have a choice of agents, and remembering the value of refreshing sleep in restoring nervous power, we may legitimately resort to chloral hydrate, or the subcutaneous injection of morphia.

One of the most useful supplementary agents we consider the Turkish bath. We do not regard it as a preservative *per se*, but it may be advantageously employed as an adjunct to mental treatment. We regard the Turkish bath as a most useful auxiliary in the medical treatment of nearly all diseases, and recognising its power in relieving the pores, and thus restoring the proper balance of the skin's function in eliminating noxious matters from the blood, in imparting general tone and elasticity to the system, we regard it as an appropriate adjuvant. Unfortunately, like many other useful measures, its efficacy has been too highly vaunted, and enthusiasts have claimed for it the place of an universal *panacea* in all diseases. We do not attach much importance to the case of Dr. Buisson, for his description of his sensations is not in accordance with that furnished by the majority of observers ; and some of his facts, as that a patient can drink when blindfolded, are not verified by practical experience. We have, however, abundant testimony furnished by those who have been bitten, and who, after adopting the preservative measures we have mentioned, have been nervous and alarmed, in its favour. They were restored to a positive sense of security by the use of the bath.

From inquiries we have made at numerous baths, we have gathered a large amount of information confirmatory of this view. We need not particularise the various details connected with the Turkish bath, as it has become almost a necessity of modern life, and we presume there are few medical or laymen who are not thoroughly acquainted with the *modus operandi*.

As free and copious perspiration has been advised and regarded popularly as a safeguard, it is secured in the fullest extent by this system. No contra indication existing (as in women, menstruation, advanced pregnancy, &c.), its judicious employment may be directed. Whilst the patient is under treatment the well-known "lyssi," mentioned by Zanthos, Marochetti, and Magistel, might be looked for ; they have not been found by the majority of observers. We have mentioned their situation, form, and the treatment adopted by those observers.

We must lastly bear in mind a very important matter mentioned and impressed by Fleming : If a person has been bitten by a dog, or if animals have been wounded by it, and the creature at the time does not exhibit any distinct signs of rabies, it is well, in order to tranquillise the minds of those chiefly concerned, and who are apprehensive of danger, to secure it properly for a number of days, say a fortnight or three weeks, before allowing it to go at large again. If it was really rabid when it inflicted the injury, it will soon exhibit unmistakable signs of the disease and die ; or it may then be killed, and every precaution taken accordingly. If the above-mentioned period passes without any manifestation of rabies, then the possibility of future disaster ensuing from the wounds is happily disposed of, and great anxiety abolished. But if the dog is destroyed without any evidence that it was suffering from the disease, then months of the most painful suspense, and even anguish, may perhaps elape before the result can be known. In these circumstances all that can be done is carefully to inquire into the aggressive animal's history, ascertain all the symptoms exhibited by it, and its behaviour immediately before and after inflicting the wound.

In any case, however, there should be no hesitation or delay in adopting the precautions just indicated to preserve those bitten from after consequences. M. Desjardine fully recognises the value of this measure. As soon, he says, as a

person has been bitten by a suspected animal; hasten to secure it so that it can do no more damage, and watch it closely instead of killing it at once, as is the custom. Give it several drops of syrup of buckthorn, and afterwards a dose of phosphorus, 15 centigrammes, reduced to powder and mixed in sufficient quantity of water. If the animal lives its healthy condition should be made known to the person, for the mind exercises so great an influence that it seems at times and in certain conditions, according to the idiosyncracy of the individual, to constitute the sole and unique cause of this terrible affection. But if, on the contrary, the dog dies, its death must be carefully concealed, or another must be substituted, in order to make the person believe the animal was healthy, and that the treatment to which he was submitted was merely adopted to dispel the fear and alarm he experienced at the seat of the injury.

We have now fully considered curative and preservative measures, and, lastly, we must deal with the most important section—Prevention.

Case CXLI.—A. C., male, æt. 9½, bitten on the right hand and leg by a dog; wound cauterised with nitrate of silver.

Result and Time of Attack.—Six weeks and three days. Fatal.

Treatment.—Chloral, bromide of potassium, injections, ice.

No *post-mortem*.

Reference.—*Lancet*, p. 421. 1877. Dr. R. Steele.

Case CXLII.— ——, male, æt. 42, bitten on the left hand by a dog six months old.

Result and Time of Attack.—Seven weeks, four days. Fatal.

Treatment.—Morphia.

No *post-mortem*.

Reference.—*Lancet*, p. 423. 1877. Mr. Rigden.

Case CXLIII.—Peter M. R., æt. 48, bitten on the left leg, below the calf, by a strange dog.

Result and Time of Attack.—Eight months. Fatal.

Treatment.—Chloral hydrate, bromide of potassium.

No *post-mortem*.

Remarks.—The patient said he felt fully convinced that the wound had nothing to do with his present symptoms, as he knew the dog that had bitten him was not mad, but was alive at the present time.

Reference.—*Lancet*, p. 424. 1877.

Case CXLIV.—C. J., a mason, æt. 17, bitten on the thumb and ball of the left hand by a dog supposed to be mad. The wound was cauterised with nitrate of silver.

Result and Time of Attack.—Two months after. Fatal.

Treatment.—Injection of morphia and chloral by enema.

There was no *post-mortem*.

Remarks.—This makes the third case of hydrophobia occurring in Devon in 1877, where it had been previously unknown. As is generally the case, there was no fear of water or any liquids, and it was only when a patient tried to swallow that a paroxysm came on. The mere idea of swallowing anything was sufficient to set up violent paroxysms. There was a gradual increase of temperature up to 103° F. from 99°, above which it never went, and this rise of temperature coincided with the development of the disease up to its most acute and characteristic appearance.

Reference.—*Lancet*, p. 567. 1877. Dr. Adams.

Case CXLV.—Arthur C., æt. 2 years and 9 months, bitten by a stray dog, which had bitten three other dogs. The wound was a lacerated one, at the side of the right elbow, it was cauterised with nitrate of silver, and dressed within two hours of the time when the bite was inflicted. It healed up very readily, leaving a slightly raised and thickened cicatrix. The child frequently spoke of the dog, showing that the recollection of the bite was exercising an influence on the child's nervous system. In this case the hydrophobic stage set in between the thirty-eighth and forty-eighth day, and death occurred before the end of second day.

There was no *post-mortem*.

Reference.—*Lancet*, p. 568. 1877.

Case CXLVI.— ——, servant, male, æt. 63, bitten on the little finger by a small terrier pup, aged three months. It was said by a veterinary surgeon to be rabid.

Result and Time of Attack.—Six months. Fatal, in seventy hours.

Treatment.—Injections of morphia.

No *post-mortem*.

Remarks.—This patient was very nervous, as during the year 1869 there had been rumours of cases of hydrophobia having occurred in the town.

"Five cases of hydrophobia said to have occurred in Halifax during the past five months." (*Lancet*, p. 213. 1869.)

The almost incredible number of four were under the care of one practitioner, upon whose accuracy of diagnosis and veracity, the register of deaths for the year 1869 is thus increased, in one class of diseases, and the total percentage of deaths from rabies throughout England in proportion to population, very peculiarly affected. The deaths in 1869 from rabies were 19. We have looked in vain through medical journals for notes of these four cases; the fifth we traced, and are enabled to give above through the courtesy of the surgeon who attended.

Reference.—For these notes we are indebted to William Nowell, Esq., Surgeon Halifax Infirmary.

Case CXLVII.—H. B., ship boy, æt. 15, bitten by a dog, merely an abrasion, across the back of the hand. Wound cauterised with nitrate of silver. The dog had bitten five or six other people, and was undoubtedly rabid.

Result and Time of Attack.—Seventy-five days. Fatal, on the first day of admission to hospital.

Post mortem.—The autopsy exhibited all the typical changes. There were muscular rigidity of the body generally, purple lividity of the tongue, injection of the fauces, œsophagus, and cardiac end of the stomach; turgidity of the arachnoid and substance of the cerebrum, cerebellum, and medulla oblongata, with many dark puncta in the various substances; spinal cord not examined.

Remarks.—Sir William Smart considers this a case illustrating the development of the disease without fear, or knowledge of the character of the injury, as the boy never suspected that any ill result would arise from the bite. The other persons bitten had not suffered. The dog had been bitten by a Chinese dog, and Sir W. Smart has found that canine madness is mentioned in Chinese medical books, and is regarded as a highly dangerous and fatal disease. They recommend the part to be cut out, and strong purgatives to be administered.

Reference.—*Lancet*, p. 565. 1877. Sir W. Smar .

Case CXLVIII.— ——, male, bitten on calf of leg, wound excised, and cauterised with hot iron.

Remarks.—This patient was well eighteen months after the date of the injury, but Dr. Balfour was informed that some seventeen or eighteen persons bitten at the same time had died within three months. They all refused treatment.

Reference.—*Lancet*, p. 599. 1877. Dr. J. Balfour.

Case CXLIX.—

Remarks.—Valleix, following Chomel, recognised three kinds of pseudo-hydrophobia.

1. Simple horror of liquids, perfectly compatible with health, and oftentimes seen during pregnancy.

2. Symptomatic hydrophobia, of which he mentions a case occurring at the Hotel Dieu. The patient was suffering from articular rheumatism, and suddenly developed furious delirium, dread of liquids, sputation, and pharyngeal constriction, dying in a few hours.

3. What he terms rabiform hydrophobia. He mentions an instance of this form which he saw in the clinique of M. Louis.

We shall have to allude to this last form again. We may here remark Mead ("On Poisons," p. 146, 1702) tells us "that authors have noticed dyskataposis (difficulty of swallowing) or hydrophobia in malignant fevers; and a common melancholy has been seen to end fatally in it. He had seen it himself in the height of a violent hysteric disorder, and also in a case in which fits of a palpitation of the heart were attended with so great a degree of it, that it seemed not to differ from the true hydrophobia."

The deaths referred to diseases of the respiratory organs were unusually high last week in all the large towns, caused probably by the fogs and low temperature which prevailed. Deaths from violence were also very heavy, particularly in London, where 71 from this cause were registered, the fog of Thursday week being responsible for several fatalities.

MEDICAL BOOKMAKING.

IN a clinical lecture on the "Relievable Aspects of Heart Disease," Dr. Moxon gives expression to a reflection that must have often occurred to some of our readers, especially those who would like to see the writing of medical books more devoted to the advancement of the healing art, than to the interests of the authors themselves Speaking of Heberden's works, Dr. Moxon said they were "truly a most valuable compendium of his life's experience, which he sat down to write when he was old, because he had seen and knew disease, not as nowadays, when doctors write because they are young, and because they want to see more of disease."

Dr. Moxon merely made this observation *en passant*, and very likely, but for these remarks, no further notice would have been taken of the subject. We shall however, make a few comments on it, inasmuch as we have long been of opinion that the fact to which the lecturer alluded is one of the worst features of modern medical literature, one which is, in these days of advertising, a growing evil. We should not complain so much of medical men writing books when they are young, if they only gave us the benefit of their life's experience when they got old. Men of ability and of ambitious pretensions, must do something to force the notice of the public, and to gain for themselves both a name and a practice. But if they flood the book market with weak compilations and worthless monographs, it should be with the intention of hereafter giving to the public something more worthy of its acceptance, in return for the confidence which it, through their first venture upon authorship, had reposed in them. Such books should really be an earnest of the author's intentions to devote much of his thought and practice to the particular subject of his work, while the work itself should be looked upon as merely a sort of portal through which he is passing into that wide field of research which he has in view, and from which he hopes to gather a full harvest. Unfortunately, this is not always the case, and if we were, after the manner of Bacon, to set down those circumstances which have prevented medical science progressing in proportion to the rapid growth and great voluminousness of its literature, we should undoubtedly have to mention among them that habit of writing before practice, instead of after practice, of which we are now complaining. Hasty compilations, vain and empty *brochures*, loose observations, opinions formed on insufficient data, all kinds of wild theories and doctrines—these are some of the tares which encumber the more solid and fruitful parts of medical literature, and which make the great field of medical science appear more cultivated and more fruitful than it really is.

There are two things wanting to make our medical literature a more true reflex of our advancing knowledge than it is at present, namely, industry and method, individual and collective. Of what may be termed collective or co-operative industry and method, we have nothing to say here. It is with the individual worker, with the busy practitioner, be he physician or otherwise, we are now dealing. It is, indeed, difficult to exaggerate the enormous amount of information that runs to waste for the want of a permanent record of it, or the good that might be done if those who have had large opportunities of seeing disease, were to follow the example set them by Heberden, and to give the profession the results of their life's experience. The advantages, too, of such a practice, would be greater now than at any former period in the history of medicine. In the time of Heberden, for instance, the differentiation and diagnosis of disease had not arrived at the state of perfection to which that department of medicine has since been brought, and the same may be said of all the other departments of medical knowledge. Physicians had then constantly to treat symptoms, and not the disease; and they were without those means of dispelling the obscurity of their cases which modern science has placed in the hands of the physician of the present day. Consequently if a hundred Heberdens had, at the time we are now speaking of, given to the world a record of their medical experience, the value to be attached to such experience would be very different from that we would attach to the clinical records of the present day. There is nothing in which medicine has so much advanced as the discovery of instruments, and other means whereby we can differentiate and localise disease, and whereby we can often most accurately gauge its extent, discern its nature and causes, watch its progress, and foretell its result. Every well educated practitioner now leaves his school and enters upon practice, furnished with instruments of diagnosis, and a knowledge of disease which can make his observations of far more value than the observations of the most experienced and accomplished physician of the last century. The stethoscope, the laryngoscope, the ophthalmoscope, the clinical thermometer, the microscope, the test tube—these, and other

means of unveiling the mysteries of disease have placed him in the best possible position to throw light upon those questions on which we must still admit our ignorance. And let us reflect for a moment upon the number of the questions for whose solution we still await the experience of many lives, and the careful and systematic records of many men who, with their notes before them, the long gathering harvest of their life's experience, sit down to write "when they are old and because they have seen and known disease, and not because they are young and wish to see more of disease." A more exact estimate of the therapeutic value of various remedies; the exact conditions under which certain agents are, or are not, beneficial; the progress of a large number of cases allowed to run their natural course, as contrasted with the progress, duration and termination of the same number of similar cases treated by presumedly effective remedies; the conditions under which life has been prolonged and even made tolerable in patients suffering from incurable disease; the number of instances in which the symptoms of a disease have varied remarkably from those laid down in systematic work; a careful record of the symptoms and *post-mortem* appearances of obscure diseases—these are some of the questions or subjects on which even the obscurest village practitioner could in the course of a long practice throw incalculable light, and gather such data as would, when added to other data, in time free medicine from many of the uncertainties with which it is at present invested. Nor need the practitioner who is desirous of contributing his share towards the advancement of his profession, and of writing a useful book at the end instead of at the beginning of his medical career, distract his attention with a variety of subjects. So fruitful is the principle of the division of labour, when aided by time and method, that if every medical man were in the course of his practice induced to settle, as far as he could, any one doubtful point in the subjects of diagnosis, or prognosis, or therapeutics, with the view of hereafter publishing his life's experience on that one point, he would do immeasurably more good in the cause of scientific medicine than if he had written the most learned dictionary or treatise of his age. We might then hope that the time would come when we should hear no more of rival systems of medicine, and when all the truth should be sifted from the falsehoods of allopathy, of homœopathy, of hydropathy, &c., and gathered up into one positive whole of scientific medicine. Pathology is a grand department of knowledge, which can well be left to the fortuitious labours of such able investigators as those who have already distinguished themselves by their research in that direction. But after all it is upon our knowledge of prognosis and treatment that we must chiefly base our claim upon the confidence of the public, and our reputation as useful and indispensable members of society; and it is in these very departments of the healing art that so much valuable information might be contributed by every practitioner if he would only take to heart Dr. Moxon's very just animadversion, and resolve, after the manner of the great Heberden, to leave as a legacy to those who come after him, the results of his life's experience.

"THE COMING MAN."

UNDER this strange, and, as we shall presently see, rather deceptive title, the *Daily Telegraph* of last Thursday, devoted two columns and a half of large type to one of those rambling lucubrations with which Mr. Charles Reade has recently favoured that journal. It is, indeed, difficult to see the *raison d'etre* of the great novelist's letter. It is one of those productions which have neither a beginning, a middle, nor an end, in which it is difficult to trace any order of sequence in the ideas, or to fathom the exact aim of the writer, and the several parts of which are, as regards their meaning, as much divorced from each other, as they are altogether at variance with what the reader might expect from the above sensational heading.

The "coming man" is no ideal or prophetic representation of some man whose transcendent genius is to revolutionise the world of thought, or the world of action, nor of some more perfect type of humanity to which we may look forward as the outcome of the improved physical, moral, and mental development of the human race. Nothing of the kind; nothing so flattering to human nature, or to the hopes and aspirations of all who think that a brighter future is in store for those who come after them. Mr. Reade's "coming man" is merely a man who can use his left hand as well as his right. The first part of his letter is taken up with reflections on the large amount of time, and labour, and money, that is devoted to the adornment of the body, and to physical gratifications, as compared with the insignificant attention that is given to the improvement of the mind. If, therefore (for such is the curious line of argument), the body is to receive so much consideration as to constitute "nine parts of the human being," let us by all means cultivate it with all our might; in short, let man no longer be considered, a right-handed man. "In a word," says our philosopher, "I believe that the 'Coming Man' is the Eitherhanded Man; that is to say, neither 'right-handed' nor 'left-handed,' but a man rescued in time from parroted mothers, cuckoo nurses, and starling nursery-maids, with their Pagan nursery rhymes and their Pagan prejudices against the left hand—in short, a man as perfect in his limbs as his Creator intended, who has been a deal kinder to man than man has been to himself." Then follows a long historical retrospect to show that man has never been anything else but right-handed, which the writer very naïvely confesses to be a "true statement, and an imposing one against myself." Lastly, the letter comes abruptly to an end by the writer expressing his indignation that mothers and nurses should check infants in the use of the left-hand, and "do their best to make a Pagan tradition an immortal truth, and keep mankind one-handed and right-handed."

Such is Mr. Reade's "Coming Man." He is simply to be ambidextrous; an accomplishment which is, we may infer, Mr. Reade's ideal characteristic of the future of humanity. That man was originally ambidextrous is not at all improbable, and that habit, extending its influence through many generations has, in this respect become a "second nature," is on physiological grounds, very intelligible. But what, we may ask, would man gain by returning to his original state of ambidexterity? If the

"coming man" cannot boast of anything better than this accomplishment, we shall scarcely envy the future in store for our posterity. It would have little or no effect in improving man's physique. It would have no influence at all upon his mental or moral culture. It would have very little effect in connection with the arts of life. On the contrary, those arts, the perfection of which depends upon the nicer and more complex movements of the educated right-hand, would actually suffer by the change. If the right-hand has been allowed by habit to become far more dexterous than the left, we must bear in mind that this concentration of expertness in the right member, has, through the accumulated results of hereditary influence, endowed that member with a potentiality of function which could never have been attained by the indifferent use of either hand. We shall not, therefore, share the disgust which Mr. Reade feels at the use of the infant's hands being left to the tender mercies of "parroted mothers and cuckoo nurses," nor look forward to that age, as a golden one, when the "Coming Man" is able to use his left-hand as well as his right.

Notes on Current Topics.

Treatment of Phymosis in Boys.

Dr. L. M. Yale, in an article in the New York *Medical Journal*, considers phymosis as physiological in childhood. It demands treatment only when it sets up direct or indirect irritation. Simply breaking up of adhesions, the forcible retraction of the prepuce with or without its division, divulsion of the preputial orifice, and complete circumcision, are the various methods that have been employed. Bókai, who only interferes if there be pathological symptoms, relies solely upon retraction, breaking up the adhesions with a probe or other suitable instrument. Inflation of the prepuce with water forced from a syringe, is recommended for the same purpose. Dr. Holgate informs me that in all his cases—a great number—he has found forcible retraction sufficient. The glans, after being cleaned of smegma, is anointed, and the prepuce again brought forward. In this, he agrees exactly with Bókai. This manœuvre is repeated by the surgeon, if necessary, and the attendant in any event directed to repeat it daily. One instance he mentioned of recurrence twice of the enuresis, owing to the agglutinations having been allowed to re-establish themselves. In such a case circumcision will probably make a complete cure.

If the prepuce be redundant, circumcision is the preferable operation; if not, splitting of the prepuce, if necessary may be done to assist its retraction. In adolescents, or in children, where the prepuce has been the seat of much inflammatory process, the knife will be generally needed in one method or the other.

Dr. Sayre urges the necessity of circumcision, and of doing it thoroughly, watching carefully for constricting bands of mucous membrane, and nicking them if they exist, dividing, also, the frenum if it be short, &c.

Phenicated Camphor in Diphtheria.

Dr. Souley lately called the attention of the Société de Thérapeutique, of Paris, to the great utility of this substance as a local application in those cases of diphtheria in which the deposits of false membranes constitute the initial and chief phenomenon—the danger arising from the steady and rapid propagation of these membranes, or the ulterior intoxication of the economy. Under the contact of the phenicated camphor, says the *Journal de Therapeutique*, the pseudo-membrane seems to lose its vitality, without that irritation of surrounding parts being produced, whether of the skin or mucous membrane, which is almost always caused by the various solid or liquid topical applications now in use. The solution employed by Dr. Souley is formed by dissolving powdered camphor in crystallised carbolic acid previously dissolved in alcohol (nine parts of the acid and one of alcohol), and which may be employed either in its pure state, or mixed with equal parts of sweet almond oil. He related four cases in support of this mode of treatment.

Explosive Inspectors in Ireland.

It may be in the recollection of our readers that about twelve months since we referred to the appointment of an Inspector of Explosives in the Castlebar Union at a substantial salary and with almost no duty of any sort to do, at the same moment that the sanitary officer of the district could only be paid £5. It turned out on further inquiry, that the appointment had not been made by the guardians, although the payment was to be made by them, it being the law that the magistrates should appoint and name the salary, and that the guardians should pay.

We observe that this Act has been made the occasion for disgraceful jobbing in many localities in Ireland, appointments having been made in numerous instances where there was absolutely no inspection to be done. For instance, we find the following in the proceedings of the Ballina Guardians.

"Here a magisterial order for payment from Crossmolina. Two magistrates have signed an order, forwarded to me as follows:—"Pay to Mr. James Nolan the sum of £2 10s. for his salary to 31st December, due to him for carrying into effect the provisions of the Explosives' Act."

Mr. Cormack—I don't suppose there is one pound of powder in the whole town of Crossmolina.

Chairman—We should memorialise the government against this imposition.

Mr. Mostyn—This is a monstrous charge upon the rates.

Chairman—I cannot believe it is compulsory on the magistrates to make these appointments where there is no sale of powder. Before making those appointments I would say the first duty of the magistrates is to inquire if there is any sale of powder.

Mr. Dillon—None of these small towns require inspectors.

Mr. Mostyn—Westport is one of the towns that stand in the same category as Ballina, where there is a sale of powder. Well, the appointment of inspector was first made in Westport, and there Lord John Browne wisely fixed the salary as low as £5, [which is all that is given.

If this was a wise and just arrangement for Westport, you can calculate what the salary should be in a Crossmolina, Foxford, and the other small towns.

Mr. Thompson—If this came as a bill before us I would decline to sign the cheque till I should ascertain what the duties are which are discharged.

Chairman—The unreasonableness of the thing ought to be brought before the magistrates of the county. I think myself there must be a discretionary power given the magistrates. The Act was scarcely at all required, as previously there was sufficient machinery in operation to control the sale of explosives, and in Ballina, the Town Commissioners exercised a very close supervision, as I have reason to know.

Clerk—This will go before the Treasurer, and he will know how to deal with it.

Tobacco Smoking in Workhouses.

After what we lately said on this subject our readers will not be surprised to hear that the Board of a large London workhouse—the Holborn Union—have recently sanctioned a recommendation that a portion of the inmates shall be permitted, under certain restrictions, to smoke tobacco. The General Purposes Committee of the Board brought up a report stating that they had invited the medical officers of the union to assist them in considering whether smoking should or should not be tolerated. Dr. Jarrow, of the City Road workhouse, said that smoking was permissible in certain chest affections. Mr. Norton, of the Gray's Inn Road workhouse—the infirmary of the union—stated that many consumptive patients had been allowed to smoke, and no complaints were made by the non-smoking patients that the practice was offensive to them. The sick people generally found their own tobacco, but Mr. Norton had ordered it for the solace of lunatics and imbeciles. Acting upon these and other representations, the Committee advised the Board to allow smoking in certain wards at duly allotted times and seasons. The helpers are also to have a smoking-room of their own away from the main building, to be used after work is over. Eventually, the recommendation of the General Purposes Committee were agreed to by the Holborn Board of Guardians. It will not be disputed that smoking is a luxury which should hardly be looked for within the walls of a workhouse. Nevertheless many of the inmates of these houses have been in the habit of smoking for years, and to be suddenly deprived of such a gratification would amount almost to a punishment, and make their position seem much harder than it is. The concession, therefore, now granted is a very philanthropic one, and in the making of which we recognise a tacit admission that tobacco-smoking is, when practised in moderation, a great boon to a large section of the community, and a consolation which can find admittance where all other consolations are excluded.

There was an alarming rise last week in London of deaths from small-pox, equal to 40 per cent. above any week for the past six months. Of the 51 deaths, 25 were certified as of unvaccinated persons, 14 as of vaccinated, the remaining 12 giving no certificates as to vaccination.

A Medical Amendment Act.

We understand that a Government Bill for the Amendment of the Medical Act is in course of preparation, and will be brought in as soon as it has been submitted for approval to the General Medical Council, which is to be called together at an early date—probably early in March—for its consideration. The nature of the Bill has not transpired, but it may probably be intended to make law of the resolutions respecting foreign diplomas to which the Government and the Council gave utterance last year. Dr. Lush has again given notice of his intention to introduce—in a modified form—the Bill which—at the instance of the East London Medical Defence Association—he laid before the House last year. He has, however, removed from it the clause which caused such a panic amongst the prescribing druggists, because it laid a penalty upon unregistered and unqualified persons who practised medicine for gain. It may be recollected that we earnestly discouraged the challenging of the verdict of Parliament at this point, not because we had any doubt that the community would greatly benefit in the long run by an absolute prohibition of unlicensed practice, but because we were aware that the temper of Parliament was utterly averse from so strict a measure, and that the influence of the prescribing druggists was more than sufficient to prevent its passing. The Bill is set down for its second reading on the 20th of February, and before then we shall inform our readers further about both the measures to which we have referred.

Inebriate Asylums.

The public feeling and that of the medical profession in favour of the restraint of dipsomaniacs, for the purpose of curing them, has become so strong, that we hope to see before long some effective legislation on the subject. It will, therefore, be of interest to print in abstract the Act which has been in force in Victoria for the same purpose during the last five years, and which has been found free from serious objection in its working. The following are the principal provisions of the Act:—

The third clause empowers the Executive to grant a licence for twelve months to any person or persons to keep house for the treatment and care of habitual inebriates, to be called a "Retreat."

Fourth refers to admittance.—"Any person desirous of being committed to a Retreat may make application to any justice, and such justice if he be satisfied that the applicant has habitually used excessive quantities of intoxicating drinks, and that he is at the time of his application sober, and that he fully understands the nature of his application, may make an order authorising the apprehension of such person, his conveyance to some Retreat, and his delivery to the superintendent or other proper officer thereof, and his reception, detention, and curative treatment therein for any term not exceeding twelve months."

Fifth provides that any County Court judge can, on the application of any friend, relation, or friend of any person addicted to the habitual use in excess of intoxicating drinks, issue a summons for his appearance before him.

Sixth. If upon hearing of such summons in the presence or absence of the inebriate, it appears that by reason of his abuse of intoxicating drinks, the person summoned is unable to control himself, and is incapable of managing his affairs, or is dangerous to himself or to others, or is suffering under or recovering from delirium tremens, or chronic alcoholism, or is in imminent danger of death from the

continuous use of such drinks, and if two medical practitioners certify by statutory declaration in writing that such person requires curative treatment in a Retreat, the judge may make an order authorising the apprehension of such person, his conveyance to some Retreat, and his delivery to the superintendent or other proper officer thereof, and his reception, detention, and curative treatment therein for any term not exceeding twelve months ; or such summons may be dismissed with costs as against the applicant.

Seventh provides that any judge of the Supreme Court can rescind order.

Ninth provides for the payment by the inebriate of all costs and expenses of cure.

Tenth refers to the discharge of inebriates at any time before the expiration of the term.

Pyretic Saline.

In the English Court of Appeal last week the case of the Attorney-General *v.* Lamplough came on for hearing. This was an appeal by the defendant from the Exchequer. The case came before that court under the following circumstsnces :—The Attorney-General had laid an information charging Mr. Lamplough, that he did "expose and utter and vend a bottle of medicine containing a certain preparation to be used and applied as a medicine or medicament for the prevention, cure, and relief of disorders and complaints incidental to and affecting the human body, called Lamplough's Effervescing Pyretic Saline, wherein he had, or claimed to have, an occult secret or art for making and preparing the same," and that he did so sell it "without the cover, wrapper, or label provided by the Commissioners of Stamps for denoting the duty chargeable on such bottle." The information came on for trial at Westminster, when a £10 penalty was imposed, subject to the opinion of the Court above on a point of law. The question accordingly came on for argument, the Chief Baron being of opinion that the preparation in question was not a medicine within the meaning of the statute, while two other judges took a contrary view, and gave judgment for the Crown. From this decision the defendant now appealed. The 52nd Geo. III., c. 150, so far set forth the articles to be taxed, and under the heading "waters" appeared all artificial waters impregnated with soda, or mineral alkali, or carbolic acid gas, and all compositions in a liquid and solid state. "Lamplough's Pyretic Saline" is composed of tartaric acid, bicarbonate of soda, and a small quantity of chlorate of potash, and it was admitted that it formed an artificial mineral water when the ingredients sold in a solid state were mixed with water. For the defendant it was contended that pyretic saline was a beverage which was, in point of fact, an artificial mineral water, and therefore exempt from duty, and that, if so charged, Schweppe's soda water and lemonade and all others of the same kind, would be chargeable ; while for the Crown it was submitted that it did not come within the provisions of the repealing act as an artificial water, but the contrary, as its sale depended on its medicinal properties.

On the conclusion of the arguments their lordships delivered an unanimous judgment, holding that it was the intention of the legislature "to exempt all these waters from taxation, even if the venders held that they were beneficial for human ailments, and therefore that the pyretic saline was not chargeable with duty."

Small-pox in the Metropolis.

Since the outbreak of the small-pox epidemic some few months, when the deaths were as high in one week as one hundred and forty-eight from this disease, there has been a steady diminution of cases to about a dozen in one week in December. It was then thought and hoped that the disease had well nigh ran its course so far as the Metropolis was concerned, and several of the temporary hospitals were closed under this impression. Latent seeds of mischief, however, were still in existence, which have suddenly developed into such proportions as to lead to the fear of another serious visitation, and the Asylums Board are preparing for the contingency by re-opening the closed buildings. The following is a summary of the cases under treatment during the past fortnight at the various small-pox hospitals under the management of the Asylums Board :—Admitted, 261 ; died, 42 ; discharged, 166 ; remaining under treatment 495 ; totals for the preceding fortnight—admitted 242 ; died, 40 ; discharged, 183 ; remaining under treatment, 405 ; showing a total increase on the number remaining under treatment of 90.

Petroleum at Lisdoonvarna.

We find it stated in the local paper that the inhabitants of Lisdoonvarna were lately thrown into a state of the wildest excitement by the discovery of a paraffin spring. The announcement of so important a discovery soon attracted a large number of the inhabitants to the spot from which the oil was oozing, and several of them carried away vast quantities of the fluid. It emits a clear light and is somewhat thicker and darker in colour than oils usually sold under the name of paraffin. The water from the surface of the adjoining land has impregnated the oil as it emanates from the well, and on this account it would be difficult to form a correct estimate either of the quality or the extent of the supply.

Suicide of a Guy's Hospital Student.

We understand that a student committed suicide at Guy's last week by shooting himself. The cause of this terrible step is supposed to have arisen in consequence of the difficulties presented to the filling up of his schedule for the second college examination. We believe that considerable dissatisfaction exists at several of the large London medical schools amongst the students, on account of the refusal of the teachers to "sign up" a man, unless morally certain that he will pass the college. This is notably the case at Guy's, where this otherwise sensible course is said to be carried to extremes. We would counsel the authorities to investigate the matter.

The Action of Mineral Water Baths.

At a recent lecture held at the Budolphinum, at Vienna, before a large audience, Dr. E. Lewy, says our contemporary, *Nature*, proved that the human skin is completely impenetrable for the chemical contact of mineral waters, and that therefore the explanation of the effects of baths in these waters, at the numerous bathing-places, has to be sought exclusively in the domain of physics, and not in that of chemistry. This important discovery annuls all common views regarding the bathing cures effected by the

various mineral springs, and explains in the simplest manner that, from a chemical point of view, the action of the most opposite waters must be one and the same.

Cork Street Fever Hospital, Dublin.

At the last meeting of the committee, the registrar reported 18 cases of small-pox in hospital. The committee proceeded to the election of the medical staff for the ensuing year, and the following was the result. Permanent physicians—C. F. Moore, M.D., and J. W. Moore, M.D. Temporary physicians—Reuben J. Harvey, M.D., and William Stoker, L.K.Q.C.P.I. Surgeon—James H. Wharton, M.B., F.R.C.S.I. Dr. Grimshaw completes his full term of seven years as permanent physician, and retires on 31st of March next, according to rule.

The sixth meeting of the Ulster Medical Society, was held in the Royal Hospital, Belfast, on last evening, the 29th January. Business :—Dr. Harkin to read notes of a case of Psoriasis of nine years standing, speedily cured by Chrysophanic Acid, and will show the patient. Dr. Whitla to exhibit a patient treated with Chrysophanic Acid. Dr. Esler to read a paper upon "The disposal of the dead." Dr. Core to read notes of a case of Glosso-Laryngeal Paralysis, with Progressive Muscular Atrophy. Professor Dill "Version *versus* Forceps, and Notes on other Obstetric Operations, suited to the different degrees of Pelvic Contractions, including Gastro-Elytrotomy and Ablation of the Uterus.

It is stated in our contemporary *Nature* that—"The influence on the animal organism of breathing pure oxygen gas of density corresponding to ordinary atmospheric pressure has not hitherto been adequately determined. The Royal Society of Göttingen therefore offer a prize on the subject, made both on homoiothermal and, as far as possible, on pockilothermal animals. In these researches, while certain externally visible phenomena in the animal will have to be considered, special attention is desired to be given to the nature of the blood and the exchange of material excretion of carbonic acid, and nature of urine. The oxygen used should be carefully freed from all foreign matters apt to occur in manufacture, while a limited, and, perhaps, hardly avoidable admixture of atmospheric nitrogen would not compromise the result."

The King and Queen's College of Physicians in Ireland have announcced that their Course of Scientific Lectures for 1878 will be delivered in the College Hall, at five o'clock, p.m., on each Monday in the six weeks, commencing Monday, 4th February. The following are the lecturers :—Walter G. Smith, M.D., Dubl. ; F.K.Q.C.P.I. ; Assistant Physician to the Adelaide Hospital. Subject : "The Principles of Electro-Therapeutics."—John Mallet Purser, M.D., Dub. ; F.K.Q.C.P.I. ; King's Professor of the Institutes of Medicine. Subject : "Researches in the Anatomy and Physiology of the Spinal Cord."—Thomas Wrigley Grimshaw, M.D., Dubl. ; F.K.Q.C.P.I. ; Diplomate of State Medicine, Univ. Dub. ; Physician to Steevens' and Cork Street Fever Hospitals. Subject : "The present state of our knowledge of the Intimate Pathology of Contagion and its relation to the prevention and treatment of Zymotic Diseases."

A special meeting of the Whitehaven trustees was held on Wednesday last, to consider the sanitary condition, and what measures should be adopted to eradicate the fever which prevails so extensively in the town. It was resolved to send notices to all owners of property in infected districts to disinfect their property, and put their houses in a proper sanitary state, wherever the medical officers consider it necessary to burn bedding and clothes. A building is also to be hired, were patients may lodge till their homes are placed in proper sanitary condition.

At Manchester Assizes last week John Campbell White, surgeon, was indicted for having administered a noxious drug to a girl named Coy, and used instruments, with intent to procure abortion. William Johnson was indicted for aiding and abetting him in the same. Coy was a domestic servant in the employment of Johnson. She was seduced by him, and was subsequently taken by him to a house where she was treated by White. White was house-surgeon at Ancoats Dispensary. They were found guilty, and sentenced to five years' penal servitude each by Mr. Justice Denman.

The verdict returned in the case of death from chloroform which occurred at the Devon and Exeter Hospital last week, was "homicide by misadventure during an operation." The Coroner assured the house surgeon that no negligence was attributed to him by the verdict, as every care and attention had been shown, death being the result of an accident which could not be foreseen.

Their Royal Highnesses the Prince of Wales, and Duke of Connaught, have forwarded donations of £10 10s. and £20 respectively, to the Committee of the National Orthopædic Hospital of Ireland, 7 Upper Merrion Street, of which Institution their Royal Highnesses have been graciously pleased to become Patrons.

There is said to be a section of the inhabitants of Greenock who are very earnest about the question of Latin prescriptions, and they are taking the opportunity of an impending parliamentary election to obtain pledges from their numerous suitors to vote for a decree that all medical prescriptions shall be written in English.

The death-rate in St. Petersburgh continues to be very excessive, the number returned last week being 46 per 1,000 of the population, nearly double that of the average of all the large cities in the United Kingdom, and higher even than Bombay.

We understand that Mr. Samson, surgeon in charge of the Russian wounded at Bucharest, has received the decoration of the Star of Roumania in recognition of his services.

Correspondence.

MORTALITY OF ABSTAINERS AND MODERATE DRINKERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The paper noticed in your leading article last week, under the above heading had, for its original object, the examination of 1,000 deaths occurring among insurants within seven years after medical report and acceptance as practically sound lives. These medical reports were all from registered medical practitioners, a full declaration as to family history and personal antecedents having been submitted to the medical examiner.

For claims based on these 1,000 deaths, the Temperance and General Provident Institution paid out about £200,000, the policies in many cases becoming payable for deaths certified as due to lung disease, cancer, &c., within a few months after payment of a first premium. In many instances, such deaths were obviously only the normal development of conditions which probably existed at the time of passing medical examinations, and in some of these there must have been fraudulent concealment or misrepresentation by the proposer to the medical examiner. I need not point out that the entrance of such lives would, in a small society, produce insolvency, and that they are always a fraud upon provident insurers whose bonuses are trenched upon for the payment of such claims. Other claims there were, deaths from zymotics, from railway accidents, &c., which serve only to illustrate the equitable and benevolent operation of a sound system of mutual life assurance. The investigation of premature deaths, such as these in lives recently certified as sound, must have large interest, and the results will arm medical men for the more complete prevention of frauds. But as I am tabulating an additional series of deaths, I will not now go into that topic.

As to the comparative mortality of abstainers and moderate drinkers, the Temperance and General Provident Institution has always contained a large section of total abstainers. Its success during the 38 years of its existence has been so great that, after paying out vast sums to the widows and children of deceased members, it had, at the end of 1877, £2,309,000 accumulated as the savings and property of surviving members. Its work for the year 1877, showed receipts £328,000, out of which after paying the year's claims, no less than £182,000 was added to its accumulated savings.

No doubt these results have been largely due to judicious management of the funds, and to the high character generally of the managers of the Institution. Still the fact remains that a very large proportion of abstaining insurants are collected in this society, and that in their section a surplus bonus has been divided of more than 17 per cent. beyond that divided among the moderate drinkers. This being a cash result taking the ages and all actuarial considerations rigidly into account, and this difference having continued over every adjustment of bonus between the two sections, medical considerations arise which are of great interest. These two sections of the insurers are designated the "General" and the "Temperance." In the general section are included all lives not declaring themselves abstainers, while all persons prone to drinking habits or showing evidence of previous damage from the use of alcoholic beverage are declined.

The General section of this Society should fairly represent the best class of moderate drinkers. In the Temperance section are included all accepted insurers who declare themselves to be total abstainers, but in all other respects, the lives in the two sections are indistinguishable from each other, while their premium rates, and their ratio of the management expenses, are the same. The death claims of the moderate drinkers are paid out of the fund belonging to their section while the death claims of the abstainers are also paid out of the fund accumulated from their own premiums. In each section the balance accumulates to meet the claims of survivors, and the surplus is divided as bonus. As I have already stated, the actuarial cash result is that owing to a smaller proportion of death-claims among the abstainers, there has been a surplus bonus to divide in their section of above 17 per cent. more than that of the surplus left among the moderate drinkers.

Taking an equal number of deaths from among the abstainers and moderate drinkers, the mode in which the mortality is distributed over the various causes of death is extremely interesting. But it is necessary to bear in mind that the death-rate from particular diseases as *among equal numbers of entrants*, is quite a different thing to the distribution of *an equal number of deaths* over various causes of death. It is to the latter alone that the examinations of the 1,000 actual deaths refers. In round figures the following results come out:—Diseases of the nervous system, and of the excretory organs, killed 112 abstainers for 186 moderate drinkers, the excess of mortality of the moderate drinker being 74-112, or 66 per cent. Lung diseases, heart diseases, zymotics, and casualties, killed 461 abstainers, for 401 moderate drinkers, showing an excess of mortality under these heads among abstainers of 60-401, or 15 per cent. It is obvious that abstainers must die of something. Those not prematurely cut off by disease of nervous system, or of excretory organs, must come out under other causes of death, while the moderate drinkers, prematurely cut off by these diseases, represent suppressed factors that otherwise must have gone to swell the totals from normal disease. So far as these 1,000 deaths go, we see that out of equal numbers of deaths among abstainers and selected moderate drinkers, the moderate drinkers are cut off by decay of nerve and destruction of excretories, to the extent of 66 per cent. beyond the mortality from these causes among abstainers. On he other hand, abstainers perish of diseases which, speaking roundly, may be ascribed to overwork and exposure in an excess amounting to 15 per cent.

Referring, if for a moment I may do so, to our comment upon these facts, I may perhaps say that I do not anticipate any material variation to be shown by the further statistics now being investigated, and that I think the actuarial result in the way of cash bonus is conclusive as to the respective mortality among the abstaining and general sections. You think it "absurd to assume that the abstainer is more subject to casualties than the moderate drinker, as no one would contend that the former is more likely to fall down and break his leg than the latter." Doubtless these deaths do at first sight seem very puzzling. Still I think that the explanation offered by me in the debate at the Society of Medical Officers of Health is probably the true one, *i.e.*, that the abstainers, having sounder nervous systems, are more venturesome and more hardworking than the more inert moderate drinkers. A man with sound excretories will have purer blood than another, and a man with sounder nerve will experience the stronger impulses. Taking these two conditions together, you have greater energy and impulsiveness, and with those qualities you will have more deaths from fatal accident and from overwork. On the other hand, by reasoning such as that adopted in your comment, it would follow that a man was less likely to fall down and break his leg than a woman, and so, other things being equal, it might be. But other things are not equal, the man is more venturesome and exposes himself to greater hazard, and we see what might have been predicted, *i.e.*, that it is chiefly the men who actually do fall down and break their legs. Moreover, the provident carefully sifted moderate drinkers, such as those admitted by this office, are not a class that would often get into a drunken brawl or be otherwise exposed to injuries as commonplace inebriates, and I venture to think that the explanation offered by me is likely to obtain your concurrence.

Your obedient servant,

JAMES EDMUNDS, M.D., M.R.C.P.

5 Savile Row, London,

TRACHEOTOMY IN DIPHTHERIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with much interest the paper on "Tracheotomy in Diphtheria," read by Surgeon-Major Quill before the Surgical Society of Ireland, Dec. 7, 1877, and also the remarks made by some of the members present on that occasion, and should be glad to make a few comments on points in that paper and remarks which seem to be of special value.

The author puts forth three arguments in favour of the operation when the diphtheritic membrane has descended into the trachea. 1. That the further formation of false membrane seems *to be arrested by the operation*, and quotes Trousseau, who in his "Lectures" says, "they (the membranes)

disappear spontaneously." 2. That the introduction of a tube enables the false membranes to be discharged with far greater facility than if they had the entire length of the trachea and larynx to traverse, instancing the ejection of a membranous cast of the lower portion of the trachea and upper portion of the right bronchus on the second day after the operation, in the case of a boy, æt. 5½, who had been under his care. 3. That the artificial opening gives physiological rest to the larynx.

It cannot be denied that there are instances of extension of the membrane after tracheotomy, and that in many cases in which a comparative early recovery has taken place, any diminution in the quantity of the exudation was not noticed for a few days following the operation, and therefore, I cannot but think far too great stress has been laid on the first argument, and that we should rather remember that the disease, if uncomplicated, is at the most of fourteen days' duration, and also that cases unoperated upon have often an abrupt and favourable termination. To these points must, without question, be added the second and third of Surgeon-Major Quill's arguments, the second, in my opinion, being far the stronger of the two, adding to it the facility afforded by the opening in the trachea for removing any membrane by forceps, and for the constant application of remedies, such as lactic acid with lime water, to a part which would otherwise be beyond our reach. Undoubtedly, the freer access of air to the circulation exerts considerable effect on the favourable progress of the disease.

In my small work on tracheotomy and the diseases requiring the operation, I have put forward under "Diphtheria" (page 42), the three following rules, and believe that they will be found sufficient to meet the requirements in all cases :

1. "When the excessive difficulty of breathing is paroxysmal, and the pulse keeps fairly strong, operative procedures should be delayed as long as possible."

2. "When the breathing is continuously difficult, while the respiratory efforts of the patient are strong, the intercostal spaces being forcibly drawn in, and the inspiration stridulous —signs which indicate that the membrane is in the larynx, but has not passed down into the bronchii—should these indications increase in severity, the operation ought to be resorted to, and with every prospect of recovery."

3. "When the respiration, instead of being violent, is feeble, and the whole appearance, as well as the examination of the patient, show that the exudation has passed into the large and small bronchi, then, though the operation may be done, it must be considered that the probability of recovery is exceedingly small."

Dr. Quill's criticisms on the common belief that spasm is a great factor in the production of dyspnœa when diphtheritic exudation is present in the larynx are noteworthy, and I feel sure that the more laryngeal diseases become understood by an extended use of the laryngoscope, the less importance will be attributed to spasm as a cause of dyspnœa, there being at the time sufficient organic mischief in the larynx to account for the difficulty of breathing, although it cannot be entirely dismissed as a factor of dyspnœa.

Regarding the form of operation, to which attention was drawn by Dr. M'Dowell, whether it should be laryngo-tracheotomy or tracheotomy, I maintain that the former should be considered inexpedient, because in its performance the cricoid cartilage, the great mainstay of the larynx, is cut through, and should the canula have to be worn for any length of time some danger is run of setting up necrosis of this cartilage. It is rather the position of the isthmus of the thyroid gland which must decide us in our site for the operation, but this point cannot, of course, be determined until after the first incisions have been made. I am greatly in favour of making the tracheal opening below the thyroid, thereby avoiding any necessity for interference with the isthmus of the gland which would generally be required should it be thought expedient to insert the canula above the gland.

Regarding the advisability of using steam in the after-treatment of diphtheria, it would be satisfactory to know if any surgeon has thoroughly tested its efficacy by treating a number of cases with and without it. I am not in a position to give an opinion, but I am confident by personal experience that in all other diseases its use is of no benefit to the patient, but a nuisance to him and to those in attendance. Should the employment of steam be proved a necessity, perhaps the addition of carbolic acid might be found of service.

A fact of great importance, brought out by Dr. Quill's paper, was the desirability of introducing as large a canula as possible. Instrument makers do not, as yet, seem to have appreciated this fact in the manufacture of Mr. Morrant Baker's flexible (red rubber) tube, which tube bids fair to take the place of all silver canulas after the first few days following the operation, when the tracheal opening has become fairly patent.

Yours faithfully,

Devonshire Street, London, W. W. PUGIN THORNTON.

Jan. 24, 1878.

THE CLINICAL SOCIETY OF LONDON ON SCARLATINA, &c.

WE have been requested to publish the following letter from Sir Wm. Jenner (Chairman of Committee), the committee being anxious to obtain the widest publicity for it amongst the profession :—

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The Clinical Society of London has appointed a committee, consisting of Sir Wm. Jenner, Dr. Murchison, Dr. Buchanan, Dr. Broadbent, Mr. Shirley Murphy, and Dr. Cayley, to investigate the periods of *incubation* and of *contagiousness* of scarlatina, diphtheria, erysipelas, typhoid fever, mumps, varicella, variola, and allied diseases.

The committee is desirous of obtaining the co-operation of medical officers of health, medical officers to schools and other institutions, and practitioners of medicine throughout the country, especially those practising at a distance from the large centres of population. These gentlemen, it is believed, have especial opportunities of observing facts bearing on the subjects of the present inquiry.

The committee, therefore, invite you to assist it by furnishing the particulars of any cases which may have come under your observation, in which any of the points mentioned above appear to be settled. In giving the details of such cases, all possible sources of fallacy which might vitiate the conclusion should be taken into account ; and, in particular, the possibility of the poison being conveyed by clothing, articles of clothing, &c., rather than by infected persons.

The object of the investigation, which is of the greatest practical importance, can only be obtained by the collection of a large number of facts ; the committee, therefore, hopes that all who have it in their power will contribute their aid.

A single case, in which the dates of exposure to infection and the appearance of the first symptoms can be accurately fixed, will be considered of importance by the committee.

All communications should be addressed to the Hon. Sec., Dr. Cayley, 58 Welbeck Street, W.

I remain, yours faithfully,

WM. JENNER,

January, 1878. Chairman of the Committee.

THE ADELAIDE HOSPITAL, DUBLIN.

WE learn that Dr. Albert Walshe has resigned his position as surgeon to the Adelaide Hospital, Dublin, which he has occupied for upwards of twenty years. Dr. Walshe was one of the medical staff who re-established the hospital in the year 1858, and he has been actively connected with both its medical and general administration since that time, so that his retirement will be a serious loss to the institution. We understand that for the surgeoncy thus vacated there are four candidates : Dr. Montgomery A. Ward, who for the last ten years has occupied the assistant-surgeoncy of the Hospital, Dr. Kendal Franks, Dr. W. Stokes, and Dr. Ball.

We hope we shall not be conceived to interfere unduly in the affairs of the hospital, or to express an opinion in the least adverse to the professional claim of any candidate, if we avail ourselves of the opportunity to enunciate emphatically our feeling in favour of the advancement of an assistant-surgeon to the dignity of full surgeon when an opportunity offers, and when his attainments are equivalent or nearly equivalent to those of other candidates. The system pursued in all great cities but Dublin,

under which a tyro is compelled to win his spurs as subordinate surgeon before he is placed in full charge of the sick poor, must commend itself to the judgment of every one who looks to the interest of the institution and the patient. The system of lifting students from the grind to the operating theatre at one jump cannot be defended, and it has been pursued in more than one instance, and even where the competitor has some claim to experience we do not think it just to any assistant-surgeon or advantageous to any hospital that the junior officer should be set aside if his qualities will bear any favourable comparison with those of the other candidates. In London every young practitioner who devotes himself to hospital work perfectly understands that he must prove his capacity and take his turn—that if he fails to do this he has no chance of promotion, but that if he succeeds he will certainly not be deprived of the reward which he has earned by the superior personal claims of any other claimant. This is as it should be. The institution reaps the advantage of the earnest services of young and aspiring men, and the patients have the satisfaction of knowing that their adviser has been thoroughly schooled in his professional work. It is utterly indefensible to entrust the care of a hospital—as has been more than once done in Dublin—to a totally untried man on the chance that his future may justify the selection, and in the rare cases in which the act of the selectors is justified, it must receive its justification upon the "vile bodies" of the patients.

THE QUEEN'S PHYSICIANCY AND THE REGIUS PROFESSORSHIP OF PHYSIC IN IRELAND.

The appointment of Dr. Hudson to the Physiciancy to to the Queen in Ireland, vacant by the death of Dr. Stokes, has met with unanimous approval. The recipient of the honour won his spurs as a provincial doctor, and, more fortunate than many who have been led to risk their fortune in the metropolis, achieved in Dublin a success greater than he could even had hoped for. As Physician to the Meath Hospital he occupied for many years a leading official position and, having occupied the last Presidential chair at the College of Physicians, he has now reached the summit of professional success as testified by the distinction which Her Majesty has conferred upon him. It is only a few months since that he received a mark of the favour of government by his appointment as Crown Nominee for Ireland in the General Medical Council.

The Regius Professorship of Physic in the University of Dublin is the object of great interest at present in the Irish medical world. For the successorship to Dr. Stokes in this office, four candidates are mentioned: Dr Hudson, Dr. Banks, formerly King's Professor of Practice of Medicine in the University School, Dr. Benjamin MacDowel, the existing Professor of Anatomy, and Dr. William Moore, the existing Professor of Medicine in the same School. We believe that Dr. Gordon, the President of the College of Physicians, is precluded from offering himself as a candidate, having accepted the office temporarily on the understanding that he would not be a candidate when it became vacant.

SMALL-POX IN THE ISLE OF MAN.

In the House of Commons on Monday night, the Home Secretary, replying to the interrogatories of Sir J. Lawrence and Mr. Ritchie, said, it was utterly untrue that the governor of the Isle of Man had deserted his post in consequence of the outbreak of small-pox, he had on the contrary, done what he could to mitigate it. The outbreak had been of a most virulent type, which could not be checked as the vaccination laws were not in force in the Island. A Bill, however, had just passed the local legislature to enforce vaccination, and this would immediately receive the Royal Assent.

THE GOVERNMENT AND THE PROFESSION.

In the House of Commons, on Monday night, Viscount Sandon, replying to Mr. Mills, said he was unable at present to state whether the Government was prepared to bring in a Bill for providing a Uniform Examination for admission to the Medical Profession in England, Ireland, and Scotland.

Literature.

PREVENTITIVE MEDICINE IN RELATION TO THE PUBLIC HEALTH (a).

Sanitarians may take comfort in the fact that the public mind is at length becoming thoroughly aroused to the importance of "Preventitive Medicine in Relation to the Public Health." Even the Metropolitan Board of Works has within the last few months risen to the importance of the occasion, and by a small majority of its members, determined to make an effort to supply London with water of a purer and better quality than that it has hitherto been accustomed. It is beyond the question of a doubt that the supply is not only bad, but insufficient, and far too costly. The Board of Works promise superior arrangements for the protection of life and property, and something purer than diluted sewage for the domestic uses of the inhabitants of the metropolis. This change for the better, whenever it comes about, must be fairly attributable to the efforts made by members of the medical profession, who for years have in various ways, both in their lectures and in their writings, endeavoured to impress upon the public the vast importance of a good and wholesome supply of water, and its value in relation to the public health. The changes which have been brought about in the hygienic condition of town life, and by the same means, are a marked feature of the age in which we live. "State medicine," as it is designated, is not only better understood than it was a few years ago, but it has also become a recognised sub-division of medicine. It is properly entitled to be honoured as a speciality, and this being conceded, its study will be so regarded by those who undertake the education of students in medical science.

For purposes of teaching, Dr. Alfred Carpenter's first series of lectures to the students of St. Thomas's, will in a measure be looked upon as a model. Indeed, at the outset, he tells us that he desires to direct workers in the field of preventitive medicine, "as to the lines they should pursue for the attainment of the object, the means within reach whereby we may more successfully grapple with disease, diminish its gravity, and impede its progress."

In a work of the kind, recapitulations are unavoidable, scarcely amounting to a fault, in a lecturer who has had some experience of the necessity of reiterating a fact before it was made to tell in the slightest degree upon public bodies or local magnates. The inequality of the matter of the several lectures, however, cannot be so lightly passed over, and this amounts to a fault in a man of the author's intelligence and experience. The lecture, for instance, "On Air," is vague and indefinite; and the scientific description of its composition might undoubtedly have been improved before the lecture was sent to press. That "On Water," is

(a) "Preventitive Medicine in Relation to the Public Health." By Dr. Alfred Carpenter, M.D. Lond., &c. Simpkin and Marshall.

decidedly better; but although it contains much useful information, the directions for its analysis are not up to the mark. Dr. Carpenter seems to have formed no definite ideas of the necessity of regarding organic matter and organic carbon as very different qualities and quantities in his analysis. And we certainly cannot agree with him in his statement regarding the suspended matters in river waters. He thinks that living organisms, as "amœba, bacteria, ciliated infusoria, paramecia, algæ, and such like creatures," are "innocent of evil, and perform for the water what many kinds of birds and other living things do for us in our fields." Their presence, and not their *excessive presence*, should, certainly lead us "to be suspicious of that (water) in which they appear;" water containing any excess must render the water totally unfit for human consumption. Dr. Carpenter may rest assured of this fact, that "microscopical figures of these horrid creatures" cannot be looked upon as bogies to frighten children, and he may take it from us that water abounding in animal or vegetable life will invariably contain more than the one grain of organic matter per gallon which he says is the limit of contamination for a wholesome potable water.

On the important question of the disposal of town sewage, Dr. Carpenter is more at home. He has given a considerable amount of time and attention to the subject, and, as might have been expected, the information conveyed in this lecture is useful, and strictly practical in its character. More space might have well been devoted to the consideration of other systems in use for the diposal of sewage beside that adopted in his own locality at Beddington Farm, one of the best of which is General Scott's; it is effected by adding substances to the water and purifying it by chemical precipitation. This system has been largely tried, as well as that of "intermittent filtration;" filtration through aerated soil. By this method the organic matter of the sewage is oxidised and destroyed, and the water which passes slowly through the soil is rendered comparatively pure. This is not exactly the case with the irrigation of the Beddington Farm, for the water passing into the Wandle at this period of the year is by no means deprived of all its suspended organic matter, to say nothing of the salts in solution; and it certainly is an error to say it is as pure as Thames water at Teddington Lock. Beddington Farm, however, we believe, actually produces larger crops than other farms, but for those who look to the quality of the produce, and certainly to the cost, Beddington Farm will not be looked upon as a model worthy of imitation. We should add, also, that there are not many boards of guardians to be found bold enough to follow the example of the Croydon Board. In Dr. Carpenter's opinion, however, irrigation farming does not pay, because land-owners, knowing what their land is required for, refuse to let it under double its value. Local authorities are much to blame for submitting to any imposition of the kind; it is clearly their duty to the ratepayers to resist attempts of the kind to the utmost, and they should at all times prefer to try other methods for the disposal of sewage.

Did space permit, we might pursue the question further; we must, however, content ourselves by directing attention to the concluding chapter on Sanitary Education in Elementary Schools, as this contains many useful and practical suggestions; whilst Dr. Carpenter's Address in Public Medicine, delivered before the British Association, has already been noticed in our columns; and it now forms an appropriate conclusion to a series of lectures that will be referred to by officers of health and sanitarians, and as marking an epoch in preventitive medicine in relation to the public health.

GLENGARRIFF AS A HEALTH RESORT. (*a*)

Attention has been pointedly called to the great value of Glengarriff in Bantry Bay as a sanitorium for the South of Ireland by Mr. G. P. White, of London, and the case which he makes in favour of the locality ought certainly to convince those who seek either health or the pleasures of picturesque rurality that they cannot seek these *desiderata* in a more certain *habitat* than at Glengarriff. The beauty of the situation in which the Eccles Hotel—the great caravanserai of the locality is placed—can hardly be described. It has been pronounced by so inauspicious a critic as Thackeray to be "a country of the magnificence of which no pen can give an idea. I would like," he says, "to be a great prince, and bring a train of painters over to make, if they could, and according to their several capabilities, a set of pictures of the place. Were such a bay lying upon English shores it would be a world's wonder." Sir John Forbes, F.R.S., Physician to the Queen's Household, is hardly less enthusiastic, while the testimony of physicians of the highest position is unanimously to the effect that the neighbourhood is as noted for its salubrity as for its exquisite beauty.

A local physician, Dr. Blennerhasset, gives the following statistics as to the rarity of consumption in this district. In his dispensary practice at Tralee he had only one consumptive case in 2,000, and of 163,411 patients in all, only 85 laboured under phthisical disease. He adds that this malady is still more rare among the gentry, and that the progress of the disease is slower than is usual elsewhere.

The extreme mildness and evenness of the climate of Glengarriff (which is attested by the class of plants which grow here luxuriantly in the open air, and without any protection from the weather) render it peculiarly suitable for a winter residence.

The climate of this part of Ireland is neither marked by rigour nor inclemency, the mean of the winter and spring temperature being 3½° higher than that of Montpelier, although situated 9° to the north of it, owing to the Gulf Stream which first impinges on this coast. Snow is rare, and seldom lies on the ground more than a few hours, except on the summits of the highest mountains.

The meteorological table of this district proves that the average temperature exceeds London by about 7°; Torquay, about 6°; Undercliffe, 5½°; Cove, 4½°; Penzance, 4°; the difference being still greater in the spring months. Consumption is little known in this district.

It is but recently that any facility has existed to enable tourists or health-seekers to avail themselves of the advantages of Glengarriff, but this difficulty has now been removed, inasmuch as a thoroughly well appointed hotel—the Eccles—is now open in the most beautiful spot upon the shores of the bay. It is reached from the Drimoleague Station of the Cork and Bandon line by a lovely car-drive, and is thus within attainable distance without being so easy of access as to invite the immigration of the objectionable rollicking tourist. If Glengarriff does not in time take the position of the leading watering place of the South we shall be greatly surprised.

(*a*) "Remarks on the Advantages of Glengarriff as a Health Resort and Sanatorium." By G. Preston White, Esq. Post 8vo. Pp. 48.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

THE HONBLE. GRANTLEY BERKELEY AND HYDROPHOBIA.—We have carefully perused your letter and regret we must decline to insert it. We believe your views on the subject are erroneous, and we prefer the opinions of such eminent veterinarians as Fleming, Bouley, Hertwig, &c., to whom you take exception. The name "Hydrophobia" is a misnomer, and has led to numerous errors in connection with the disease which we have termed—adopting a very old name—*Rabies*.

DR. PANTALEONI, Rome, is thanked for his communication. As, however, the information had been already placed before the profession by telegraph some days previously in the daily papers we were, unfortunately, unable to make that use of his letter we should have otherwise done.

SIR HARCOURT JOHNSTONE.—We cannot re-open the discussion in the present crowded state of our columns. When the Bill comes before Parliament a more favourable opportunity may present itself for the publication of your views.

OBSERVER.—The election being in contravention of the terms of the advertisement was undoubtedly illegal, but that would not necessarily prevent the L.G.B. from confirming it. It is not long since they sanctioned the election of a dispensary medical officer by a committee which was illegally constituted, and after they had themselves stated officially that any election held by such committee would be void. Practically, their confirmation of the election may be said to close the transaction, but, strictly speaking, it cannot legalise an illegality, and we believe a *quo warranto* might be obtained from the Queen's Bench to set aside the election. Probably, such a proceeding would be better left alone.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Wednesday, Jan. 30, Friday, Feb. 1, and Monday, Feb. 4, at 4 p.m., Prof. Erasmus Wilson, F.R.S., lectures on "Dermatology."

THE YORKSHIRE AND NORTH WESTERN ASSOCIATIONS OF MEDICAL OFFICERS OF HEALTH.—We are asked to announce that a joint meeting of the above Associations will be held at Rochdale on Friday, February 1st, at the Town Hall, for the discussion of the following subjects: "The Rochdale system of dealing with Excreta and House Refuse;" to be introduced by Dr. Wilson, M.O.H. "The Influence of the Birth-rate upon the Death-rate of a District;" to be introduced by Dr. Britton (Halifax). "Suggestions for the Amendment of the 'Public Health Act, 1875;'" to be introduced by Dr. Sutton (Oldham). After which there will be a dinner at the Town Hall. All medical officers of health in the districts covered by the two Associations are invited to attend the meeting and dinner.

DR. COOPER, Notting Hill.—Communication received, and will be considered.

DR. B. G.—Many thanks.

A DRUGGIST'S CATALOGUE.—We have received a most elaborate "Price Current" from Messrs. Richardson & Co., Manufacturing Chemists of Leicester, which is certainly unique in its way. Parts I. II., III. are composed of the various officinal and non-officinal drugs, surgical appliances, specialities, &c. Part IV., and this interests us most, is a list of 545 formulæ of pills, with their ingredients, doses, and price per gross. The very idea of over 500 different kinds of pills is, to say the least of it, suggestive of considerable energy on the part of posologists for frail humanity; or, probably, as the makers would put it, tasteless sugar-plums to tempt sufferers to swallow a boon. Be this as it may, the list will probably be much appreciated by provincial practitioners, and a well-arranged diary at the end adds to its value.

OBSTETRICAL SOCIETY OF LONDON.—Wednesday, Feb. 6th, at 8 p.m., Dr. MacCallum, "Report of the University Lying-in Hospital, Montreal." Dr. Greene, "Case of Puerperal Convulsions." And other communications.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Brady, Rathgar. Dr. Madden, Ballycastle. Dr. Walker, Bonmahon. Dr. Rutherford, Ballinasloe. Dr. Baldwin, Kilmeaden. Dr. Pantaleoni, Rome. Sir Henry Thompson, London. The Hon. Grantley Berkeley, Poole. Dr. Morell Mackenzie, London. Dr. Thorowgood, London. Dr. Carey, Taunton. Dr. Herbert Tibbits, London. Dr. Charteris, Edinburgh. Sir Wm. Jenner, London. Dr. Ashurst, Philadelphia. Dr. Boddy, Camberwell. Dr. Farquharson, London. Dr. Hart, Rotunda. Dr. Coates, Portumna. Dr. Godfrey, Dripsey. Dr. Balmanno Squire, London. VACANCIES.

Brecon Infirmary.—House Surgeon. Salary, £100. Testimonials, &c., to the Secretary on or before the 11th prox.

Chorlton Union.—Workhouse Medical Officer. Salary, £250, to be increased to £300 at the end of six months if satisfactory. Furnished apartments, but not board found. Applications to Secretary, Union Offices, Manchester.

Clifden Union, Clifden Dispensary.—Medical Officer. Salary, £90. Election, 13th prox.

Limerick Union Workhouse.—Resident Medical Officer. Salary, £200, with allowances. Election, Jan. 30.

Northampton General Infirmary.—Physician on the Staff. Testimonials, &c., to the Secretary at the Infirmary.

Queen's University, Ireland.—Examiners in Medicine, Surgery, Midwifery, Materia Medica, and Medical Jurisprudence. (See Advt.)

Royal Free Hospital.—Two Junior Resident Medical Officers. Board and residence provided, but no salary. Applicants must address the Secretary before the 30th inst. (See Advt.)

St. George's Hospital.—Surgeon and Assistant Surgeon on the Staff. Candidates must have the diploma of F.R.C.S.Eng. Applications, under cover, to the Hospital before the 13th prox.

Sligo Union, Carney Dispensary.—Medical Officer. Salary, £100. Election, 4th prox.

Tobercurry Union, Coolaney Dispensary.—Medical Officer. Salary, £100. Election, 11th prox.

Wilts Pauper Lunatic Asylum.—Medical Superintendent. Salary, £600, with furnished apartments. Endorsed applications, "Medical Superintendent," before the 12th February, to be addressed to the Clerk of Committee, Devizes.

APPOINTMENTS.

BARR, J., M.B, L.R.C.S.Ed., Assistant Physician to Stanley Hospital, Liverpool.

BRASH, E. A., L.R.C.P.L., a Surgeon to the Exeter Dispensary.

DODSWORTH, F. C., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Chiswick Urban Sanitary District.

DUKE, Dr. A., Assistant Physician to the Rotundo Hospital, Dublin.

HACON, W. E., L.R.C.P.L., M.R.C.S., Assistant Medical Officer to the Central London Sick Asylum District Asylum, Highgate.

OSBORNE, J. H., M.R.C.S.E., House Surgeon to the Nottingham Dispensary.

TURNER H., M.R.C.S.E., Medical Superintendent of the Bethel Hospital for the Insane, Norwich.

WILLAN, G. T., M.R.C.S.E., Medical Officer to the Melton Mowbray Union Workhouse and No. 2 District.

Births.

CHILD.—Jan. 25, at New Malden, Surrey, the wife of Edwin Child, M.R.C.S., of a daughter.

FOX.—Jan. 22, at Clarence Street, Victoria Park, Manchester, the wife of Dacre Fox, F.R.C.S., of a son.

Deaths.

BLENNERHASSET.—On Jan. 14, at Coolaney, co. Sligo, Rowland Blennerhasset, M.D.

COCKERTON.—On Jan. 24, at his residence in Montgomery, Henry Miles Cockerton, M.R.C.S., aged 53.

CROSWELL.—On Jan. 19, at Llandboidy, Carmarthenshire, Charles Lewis Croswell, L.S.A.L., aged 67.

DAVIES.—On Jan. 16, at the Wilton Hospital, Salford, Francis Thomas Davies, L.R.C.P.Ed., aged 28.

EDWARDS.—On Jan. 18, at St. Lawrence Road, Notting Hill, David Owen Richards, M.R.C.P.L., aged 77.

FERRIER.—On Jan. 22, at Redhill, Surrey, Constance Mabel, aged 2½ years, daughter of David Ferrier, M.D., F.R.S., of 16 Upper Berkeley Street, London.

HALL.—On Jan. 14, at Richmond Road, Hackney, Wm. Hall, F.R.C.S., aged 79.

HENDERSON.—On Jan. 14, at Westoe, Thomas Henderson, Surgeon, aged 42.

JOHNSON.—On Jan. 19, at Hildon Manor, Rock, after a short but severe illness, Samuel, second son of the late Samuel Johnson, M.D. Univ. Edin., of Foxley, aged 26.

MORAN.—On Jan. 9, at Tulsk, co. Roscommon, Patrick Moran, M.D., aged 81.

PEACEY.—On Jan. 23, at Tewkesbury, Wm. Henry Peacey, M.R.C.S., aged 59.

POLLARD.—On Jan. 9, at Charlbury, Oxfordshire, William Pollard, M.R.C.S.E., aged 83.

RITCHIE.—On Jan. 27, at 27 Newton Road, Bayswater, Charles Ritchie, late President of the Faculty of Physicians and Surgeons, Glasgow, aged 79.

WALLACE.—On Jan. 21, at Cardiff, Samuel Wallace, M.D., aged 51.

ACUTE DEMENTIA IN A CHILD—RECOVERY.

By W. H. BROADBENT, M.D., F.R.C.P.,
Physician to St. Mary's Hospital, &c., &c.

(Reported by Mr. A. C. Bridges, Clinical Clerk.)

Nelly R——, æt. 9 years, was admitted into the Alexandra Ward of St. Mary's Hospital, 21st May, 1877, in a state of great lassitude and listlessness, and suffering from headache, pain in abdomen, and severe vomiting.

Family history of parents thoroughly good. They have three other children all in good health—no history of tubercle or any special disease amongst any of them. This one has had scarlatina and chicken-pox, but only slightly, and neither of recent date. She has been a very quick child, and accustomed to read and learn a good deal for one so young. For some time before illness commenced she showed much anxiety about her lessons, which seemed to be more than she could manage. About nine weeks ago she first refused to go to school, and complained of pain in back, headache, and pain in abdomen, was several times sick—vomit being a greenish-yellow fluid. She would take only very little food, remained in bed, and gradually got into a listless condition, taking scarcely any notice of those around her. She has been under medical treatment, but no improvement has taken place.

Present Condition.—Lies completely still in whatever position she is placed, the eyes closed, taking no notice of any one, never asking for food or anything else. When asked where she has pain puts her hand to forehead and abdomen. When latter is pressed pain does not seem to be more in one region than another; whole abdomen is hard and excavated. Body is of ordinary size, but considerably emaciated. She is quite conscious, but refuses to speak even to her mother. Says "Yes" in a whisper on being sharply pinched and asked if it hurts her. Sensation intact everywhere. No paralysis.

Skin warm, dry; no eruption. Temp., 99·2.

Tongue is put out very slowly but perfectly straight; it is much furred, but moist.

Pulse 90, rhythm rather irregular, somewhat tense and not easily compressed.

Thorax, on percussion and auscultation, found to be normal; no cough; breathing rather irregular, and more abdominal than thoracic. Intercostal movement hardly observable.

Heart.—Apex beats in normal position; sounds accelerated, but fairly normal.

Liver and other organs of ordinary size.

Intellectual functions apparently in abeyance; vision good. On examination with ophthalmoscope, margin of left optic-disc found to be ill defined. Fundus red, no obvious swelling, veins large, arteries rather small. Right disc more distinct in outline. Other senses perfectly natural. Bowels are very constipated. Fæces, when passed, offensive and of a dark colour. Urine passed naturally, high-coloured and scanty, sp. gr. 1030. Urates present, no albumen or sugar.

In the first instance, she was ordered pulv. hydrarg. c cretâ rhei et sodæ, gr. viij., nocte maneque. Bowels, however, remaining very constipated, she was soon given an enema of ol. ricini et. sp. terebinth, and then a copious evacuation took place. Fæces not so dark. Pain continued in head and abdomen. Diet was confined first of all to milk and ice. Vomiting gradually ceased, then beef-tea also given. Child became more and more listless. Spinal column carefully examined, no tenderness anywhere.

On the 29th, she refused altogether to take food, would keep her mouth tightly closed; so nutritive enemas were given per rectum. No change in condition when seen in morning of this day, but at 4.30 p.m., she seemed to be perfectly unconscious, eye-lids were closed; when raised, eyes observed to be oscillating, and pupils dilated. Respiration, 90 per minute; pulse, 60, tense, and not easily

compressed. Face very pale; lips scarlet. This attack passed off in a little time.

Next day she was quite conscious again; eyes were open and breathing almost natural; could not, however, by any means be induced to speak. Day after day passed and there was no special change. Mild purgative enemas were given to make bowels act occasionally. Nutritive enemas were also administered, but as the body became more emaciated these were stopped, and in their stead a tube was passed through the nostril and posterior nares into the pharynx, and through this milk, beef-tea, &c., were injected. She disliked this process, and was induced a few times to take food naturally. Soon, however, she relapsed and resolutely refused, when the process was again adopted and answered well, for emaciation did not increase, but after some days the body certainly became more nourished. Pulse varied a good deal, some days being very slow, 50, full and regular, others over 70, always, however, of fairly regular rhythm, and the heart sounds were normal. Respirations varied much, two or three times having attacks of very frequent respirations—70 to 90 per minute. By degrees she completely closed her eyes, and would not open them or put out her tongue when asked.

Another peculiarity specially marked was her aversion to those for whom she previously showed great affection, notably her mother and Sunday-school teacher. Although she will take no notice of myself, sister of the ward, or others about her, when either of the above-mentioned comes up and talks to her, she plainly shows that she dislikes them, and puts up her hand, as much as to say, "Go away from me."

June 24th.—Ice-bag was applied to spinal column for an hour, but had not the least effect. She was still in same condition. Fed through nostrils; eyes closed; when forcibly opened, pupils found to be equal and normal. Bowels acted regularly, and urine passed naturally, latter generally containing lithates, in other respects normal. Sphincters have not been relaxed; she never passes fæces or urine, except when nurse attends to her. About this time, commenced to apply faradization. When a weak current was given, no effect produced; on a moderately strong current being applied, she uttered faint cries, but would not put out her tongue or open her eyes. A good strong current made her slowly put out tongue, but she would not or could not open her eyes. Tongue observed to be clean and moist. Galvanism was applied twice daily; she disliked it, and after some time the sound of the battery was quite enough to make her put out her tongue; could not, however, be got to open her eyes. Still fed through nostrils; body slowly gaining flesh; listless condition much the same.

On July 6th, when strong current of galvanism given, she quiveringly raised her eyelids. Eyes were looking upwards; pupils equal and normal. They were closed again directly application of current was stopped.

July 18th.—She allowed the sister of the ward to feed her with a spoon. Would not put out her tongue or move a muscle until she heard battery got ready; a much weaker current sufficient to make her open her eyes now, and they are kept open some time. If the bedclothes be pulled down and so left, after some time they are found pulled up again, and this is done by patient, though it is difficult to observe how she does it; certainly takes her a long time, and is almost imperceptibly done.

July 21st.—The child has continued being fed by mouth, and last evening, while the sister was feeding her, and coaxing her to open her eyes, she did so, without application of battery, and kept them open some time; appeared also to take slight notice of things around her. This morning she opened them of her own accord, and once put up her finger to beckon the sister, also faintly called for her. When seen at about 10.30 a.m., her eyes were wide open, and face had again quite an intelligent appearance. She could just be got to say "Yes" or "No" to questions asked. On asking if she had pain, she said "Yes," and put her hand to forehead, but not to abdomen. Puts out her tongue directly she is asked; it is moist and clean. Breathing quite natural. Pulse beating quickly, 98 per minute; fairly strong; rhythm regular. Body still emaciated, but improving. From this time up to present date (August 9th) improvement has continued. Her appetite is good; bowels regular; tongue clean; pulse 80, normal. She is gaining flesh and strength; will talk a little, and is pleased again when her mother visits her; is taken out into hospital grounds and walks about.

Dr. Blandford's account of acute dementia is the clearest and most interesting with which I am acquained. There is little need for remark on this case. Acute dementia is rare, but it is necessary to bear in mind its occasional occurrence in children, as it might easily be taken for an advanced stage of tubercular or other disease of the brain, when not only would the prognosis be altogether different but the treatment required might not improbably be left untried. In this child the early vomiting and headache, the emaciation, the apparent unconsciousness, and the excavated abdomen were highly suggestive of tubercular meningitis, but the expression in the face, a slight tremulous movement of the eyelids, and the extremely frequent and shallow respiration which prevailed while under observation, revealed the character of the disease. The fact also that she never passed the urine and fæces in bed was evidence that the unconsciousness was not real. When sensation was tested she would not shrink or cry out, but tears rolled from her eyes. The refusal of food was remarkably obstinate. * When there is actual unconsciousness, so that there is no voluntary resistance to the passage of fluids, feeding can usually be effected, even when the teeth are shut, by passing the spout of a feeder within the cheek beyond the last molar, but this method failed; the isthmus faucium was closed, and the liquid rejected. In one similar case I have known death to occur from starvation.

The perversion of the feeling was again remarkable, as shown in the aversion manifested towards the mother and teacher, to whom the child had been greatly attached. This, which was the occasion of great pain to her mother, fortunately passed off, as the child recovered; but such is not always the case. A boy who was under my care some years since suffering from acute dementia, was before the attack everything that could be desired, dutiful and affectionate at home, and highly thought of by his employer; indeed, the only assignable cause for the disease was overwork and self-denial, in order to assist his parents, and anxiety on account of his mother's illness; when he left the hospital on his recovery his character was completely changed; he was unkind at home, untruthful, idle, and thievish. His thefts were foolish, and almost purposeless, and I had on more than one occasion to give certificates to save him from imprisonment. After causing his parents much distress he was, as a last resource, made a soldier. The discipline brought him to himself, and in a very short time he was made sergeant, and came to see me at the hospital.

DEFORMITIES OF THE BLADDER AND OPERATIONS THEREFOR, WITH EXPERIMENTS RELATING TO THE ABSORPTION AND EXCRETION OF MEDICINE BY THE KIDNEYS, AND THE INFLUENCE OF CERTAIN DRUGS ON THE BLADDER MUCUS. (a)

By WILLIAM I. WHEELER, M.D. Univ. Dub.,
Fellow and Member of Council,
Royal College of Surgeons, L.K. and Q.C.P.I.; Surgeon to the City of Dublin Hospital, and Lecturer on Clinical and Operative Surgery.

I PURPOSE in this paper to mention the various malformations of the bladder (human), to give a brief outline of the causes of such, to state the various operations that may be

(a) Paper read before the Surgical Society of Ireland. The discussion will be found on page 27.

performed for the relief of some of these formations, to describe cases of vesical deformity that came under my care, the operative measures I adopted, the results of such procedure; to state experiments regarding the intervals between the absorption of medicines and their excretion by the kidneys, and the influence of certain drugs on bladder mucus, from observations on numerous cases, and the practical conclusions to be deduced.

In the order of frequency I have placed these deformities as follows :—

1. Epispadias. 2. Ectopia. 3. Fissio. 4. Inversion, Extroversion, or Ectrophia. 5. Cloacal formation. 6. Plurality of the bladder. 7. The absence of the bladder, although it may appear anomalous to class want of, under deformities.

I need not allude to the first named, but as various writers on teratology have described cases of ectopia as extroversion, and *vice versa*, it may not be altogether unnecessary to mention the differences. By ectopia is understood a want of closure in the abdominal parietes by fissure, ectopia with a slit in the bladder; by extroversion, besides the abdominal parietes being deficient, the anterior wall of the bladder is wanting; by cloacal opening, the ureters and rectum opening into a common sinus.

I shall not dwell on the first, second, or third malformation I have named, but commence with extroversion, which condition was formerly regarded as a hernia of the bladder, and to Tenon is due the credit of first describing its true nature, and the conditions which really existed. In all the cases recorded there appears to be sufficient similarity not to render a diagnosis difficult, and yet extroversion has been mistaken for nævus and malignant tumour, and on more than one occasion was about to be excised as such, notwithstanding that from birth a red mucous membrane, covered by slimy discharge, occupying the middle line inferior to the umbilicus, existed. When the diaphragm is thrown into strong action a tumour protrudes—like a hernia—and on manipulation the intestines can be felt beneath, which may be pressed back. The prominence of the tumour is thus variable, even in the same person. In infants, the space occupied may not be more than from half an inch to an inch—in adults, it may be from three and a half to four inches, and transversely four to five inches. Around these tumours may be seen the remains of a white cicatrix, which coalesces with the umbilical depression, the umbilicus is nearly always above the tumour, although occasionally, the tumour may continue above the umbilicus. On the inferior part of the tumour the urine may be observed, trickling or coming drop by drop, from the ureters, which are guarded by small papillary eminences — below these can be seen the smooth trigone; inferior to the tumour, can be felt the pubic bones, the symphises being usually separated for about four inches. If a male, a split condition of the urethra exists, the glans penis being double lobed. The urethra shows the sinus pocularis verumontanum, and openings of the ejaculatory ducts. The penis is usually shortened, the scrotum is generally circularly shaped, frequently both testes are present, occasionally they are found in the coverings of the cord superior to the scrotum; sometimes congenital hernia exists in the groins. Mr. Wood, in his paper, states that the clitoris in females, and anterior fourchette, are completely divided, and attached to the corresponding nymphæ, analogous to the division of the corpora cavernosa in the male. The ureters can be better observed in the female than male; and the same writer states that the bladder and urethra open directly into the vagina, at the upper end of which can usually be seen a properly formed os, or cervix uteri. The recti muscles are found apart below, corresponding to the division of the pubis, and breadth of extroverted bladder, and continue separated to their insertion. B. Phillips states that the umbilical depression is usually present, but it was not found in a case described by Professor Humphry, in the *Journal of Anat. and Phys.*, 1868, and dissected by him and Mr. Carver. In cases described by this last writer, and by Mr. Wood, both the hypogastric cords were present. Humphry mentions the curves of the sacrum being altered, which, instead of being concave in front from above downwards, is convex, and forms a projecting angle between the second and third sacral vertebræ. This and other osseous changes are dependent on the separation of the pubic bones. In all the cases seen by Mr. Wood, the anus was placed in front of its usual position, and often with an anterior, instead of a posterior, direction. Cases are on record in which the mucous membrane of the bladder has been divided into two lateral halves. Vrolip states a case of this kind in Todd's "Encyclopædia," vol. iv., page 951; the child lived only twenty-two days. Again, the bowel may open into the vagina or urethra, the anus being imperforate, which is called by Poppendorf, the atresia ani urethralis. I may here mention a curious deformity which lately came under my notice, namely, a case of lumbar spina bifida, with the intestine opening by its side, and fæcal matter discharging. I was asked to see the case by Dr. Byrne, and I had an opportunity of showing it to Dr. Hawtrey Benson. The child died, but a *post-mortem* would not be permitted. Such deformities as those I have mentioned above, I merely relate, as the objects of them scarcely ever live for any length of time, although Bartholin states a case in which there was neither penis or anus, and all the ingesta returned by the mouth for more than fifty years (*Hist. Anat.*, iv., page 293). In absence of the urinary bladder the uterus either terminates in the urethra, or in the rectum. Simon based his operative measures on cases of extroversion from observing the latter termination of the ureters. Binnerger describes the case of Abraham Clef, who had no urinary bladder, the ureters opening into the urethra, a stylet passed into the urethra went into the ureters alternately. In the seventh vol. of the *Philosophical Transactions* Mr. Richardson gives an account of a Yorkshire lad, who up to 17 years had never passed water through the urethra, had always enjoyed good health, the only trouble to him was the passage of the urine into the rectum, where the ureters opened, by which diarrhœa was kept up. Camper speaks of similar cases. Respecting plurality there are on record cases of two or three bladders existing, but upon examination membranous septa were only discovered. There is not any case on record of plurality of urinary bladders in the human subject as far as I can ascertain, save that described by Molenetti. In this case the woman had five urinary bladders, as many kidneys, and six ureters, two of which opened into a bladder larger than the others. The remaining four terminated in four smaller bladders, which poured their urine into the large bladder.

Having thus given an outline of some of the deformities, I will briefly state the supposed causes, and do not intend entering into the various and erratic theories propounded to explain these deformities, such as Duncan's, who believed the symphysial bones were separated by means of the over-distension of the bladder, and that the bladder itself broke open from the same cause. I will have, however, to enter briefly into embryological conditions, to explain the causes of these deformities. Amongst the numerous changes which take place in the chick on the third day we have the completion of the fore-gut and of the hind-gut, the division of the first into œsophagus, stomach, and duodenum, and of the latter into the large intestine and cloaca; also the closing of the hind-gut to form the umbilical duct, and the most significant offshoot of the digestive tract, the allantois, although at first distinctly obvious on the fourth day, has appeared in an elementary condition on the third. It may be seen as a pyriform vesicle lying in the posterior portion of the pleuro-peritoneal space—and in connection with the cloaca, by a tube-like stalk, which keeps the communication between it and the alimentary canal; both vesicle and stalk have an outer layer of mesoblast, and an inner covering or layer of hypoblast. Such can be determined at this stage of development, but of the very earliest stages there are differences in the accounts.

Von Baer thought that almost immediately after the

cloaca was formed by the enlargement of the hind cæcal end of the alimentary canal, the allantois sprung from it as a diverticulum, discernible generally about the end of third day, and that both coats of the alimentary canal formed it; this diverticulum by degrees stretched into a pyriform vesicle connected, as I before mentioned, with the cloaca by a stalk, which lengthened till the allantois became an independent body, composed of mesoblast and hypoblast.

Reichert believed the allantois was formed of two solid out-growths from the mesoblast of the somatopleure, which subsequently coalesced and became hollow. He thought it was previously connected with the Wolffian ducts.

Remak states that the allantois is formed by two solid vascular outgrowths of the body-wall mesoblast, one on each side of the median line, which project into the pleuro-peritoneal cavity near the cloaca, that they coalesce and grow till they come in contact with the wall of the cloaca, with which they unite and form a spherical body, which bears on it a furrow showing its double origin—a narrow portion of hypoblast passes into the mass, the hypoblast grows rapidly, while the mesoblastic covering is almost stationary, and only forms a thin coat over the hypoblast.

His gives a voluminous and different account of the allantois development, which is embodied by Dobrynin, who says, "when the first commencement of the hind fold takes place immediately beyond the point, where the hypoblast turns back, to its normal direction over the yolk sac, a narrow diverticulum which points backwards and somewhat upwards, is formed by a special flexure of the splanchnopleure—this diverticulum is the beginning allantois, it is lined by hypoblast, while its exterior is composed of the mesoblast of the splanchnopleure. As the folding in, to form the digestive tract, increases, the diverticulum changes its position, and is parallel with the commencing digestive tract—its cavity is separated, from that of the digestive canal, by a projection of mesoblast covered by hypoblast, both open freely in front into the splanchnic stalk. In the next stage its position is more altered, and forms a large vesicle lying immediately below the hind end of the digestive canal, its blind end projects into the pleuro-peritoneal cavity below: it was thus Von Baer observed it. At the time these changes are taking place the somatopleure is being folded in to form the walls of the body, and as the folds are carried laterally from the very end of the tail they present themselves, as seen in sections, as two ridges projecting towards the sides of the allantois; on reaching the allantois these edges fuse with its wall. Remak mistook these foldings of the somatopleure and the projections into the pleuro-peritoneal cavity for the first formation of the allantois, although they have not much connection with it."

The allantois is therefore a portion of the cloaca, which growing forward becomes an independent diverticulum or vesicle remaining with the cloaca by a narrow canal, which forms its neck. The neck and vesicle of the allantois is lined by hypoblast, while its exterior is the mesoblast of the splanchnopleure; from the first the allantois lies in the pleuro-peritoneal cavity; hence it can easily be understood that ectopia is caused by the somatopleure being at fault, extroversion by the splanchnopleure.

The first deformity of the bladder which came under my notice, was that of extroversion occurring in a female, æt. 19, Cecilia E., about five feet two inches in height, with pale and anæmic features, who was admitted into the City of Dublin Hospital, under my care on the 31st May, 1875, recommended by my friend Dr. S. Murdoch. Her state on admission was as follows: Directly above the symphisis pubis, the abdominal parietes, as well as the anterior portion of the bladder, was wasting to the extent of three and a-half inches in a perpendicular direction, and nearly three inches transversely. The symphisis was separated to about two and a half inches, and the recti muscles passed obliquely upwards, separated to the width of the extroverted bladder. The posterior internal surface of the bladder protruded through the deficiency, forming a slight prominence which was occasionally increased when the patient used any exertion. This wall of the bladder was extremely red in colour, covered in portions with viscid mucus, sensitive to the touch, and not more sensitive in any particular portion. At the middle and lower part may be observed the orifices of the ureters, guarded by little papillary eminences, both being in the same plane through these orifices, I was able to pass a probe for about three inches, without the slightest annoyance to the patient; from these openings the urine could be observed to flow, drop by drop, sometimes trickling; when the drop passed the orifice seemed to contract. The clitoris was divided into two portions, the anus was in front of its normal position, the vagina was remarkably small and only permitted the passage of my little finger. She menstruated regularly, the anterior and upper portion of her thighs were red, and in parts excoriated, from the passage of the water over them. She endeavoured to prevent its flow by keeping damp cloths over her thighs, and below the pubis. The patient being placed under the influence of ether, I performed the following operation:—The skin and tissues above the bladder being of sufficient thickness, I determined on making an umbilical flap to extend over the entire width of the bladder, the length being about four and a-half inches, and the width three inches and three-quarters. I did not dissect it down to the superior margin of the bladder, but stopped a little less than a quarter of an inch from it. I next raised two pear-shaped flaps, about two and a-half inches wide from each groin, their bases being downwards. The three flaps being thus ready for placing, I turned down the umbilical flap skin surface next the bladder, and turned the groin flaps inwards towards one another, in the middle line placed closely. The raw surface of each being upon the raw surface of the umbilical flap, I next passed through the flaps turned from the groins four hare-lip pins, which held them together, piercing the umbilical flap in their passage. I then drew together, by means of twisted and interrupted sutures, the wounds caused by the removal of the flaps, and applied broad straps of plaster from one side of the abdomen to the other, save over the flaps, over which I put carbolic gauze. The patient was now placed in bed in the semi-recumbent position, with the knees drawn up. The urine continued to trickle down, over the labia and perineum, through the small aperture left in front at the junction of the three flaps; these parts were well greased with lard, and a sponge placed between the legs to catch the urine as it escaped; the patient slept for about three hours, and awoke, complaining of the scalding of the urine where it passed over the soft tissues, I made a small channel of gutta-percha, which fitted under the edges of the flaps, and carried the water into a receptacle beyond the labia. The patient continued to do well till the fifth day after the operation; she then had an anxious appearance, refused her food, and was much out of sorts. Her temperature was 101·3 F. The flaps looked doughy as if about to slough, the edges, where the flaps were taken from, were healthy, and portions had healed. I loosened the twisted sutures by cutting the silk, but did not then remove the pins, and applied over the flaps a mixture of glycerine and balsam of Peru; internally, she got bark and ammonia in effervescence, and five-grain doses of the compound soap pill every four hours. On the following day, sixth after operation, I removed the pins, the wounds caused by flaps, were nearly healed and very healthy. The lateral flaps (those from groin), at their point of meeting, had separated, were dark in colour, and undoubtedly sloughing. The extremity of the umbilical flap presented the same appearance; suffice it to say, the flaps died, the lateral to quite half, the umbilical to about two inches. Some months after I proposed another operation to the patient, she being in a favourable condition for it, and the nucleus of the former flaps affording an assistance. She refused, unless I would guarantee complete success, the only benefit to the patient was, that the remains of the labial flaps prevented the urine from running over her thighs as before the operation.

The next case is that of a young gentleman, æt. 15 years, who was brought under my notice by a near medical relative of his. He suffered from ectopia and fissio vesicæ, with epispadias. He was pale, well nourished, walked with a widened but straddling gait. On examination I found the pubis separated the thighs more apart than normal. The mucous membrane of the bladder protruded beyond the abdominal wall, and formed, when he was in the erect position, a prominent red tumour. This was excoriated in one or two places by the rubbing of his clothes. On careful examination the ureters could be observed; the scrotum was small, both testicles could be felt in it. The urethra was a mere channel, the corpora cavernosa being imperfectly connected. The ectopia did not extend the entire way to pubis, about half an inch of closure being above the pubis. The water flowed over the thighs and scrotum, occasionally some ran along the open urethra. This happened when he was in the erect position. He had worn an apparatus, but states he felt more comfortable without it. In December, 1875, I operated on this case, turning down a large umbilical flap and two pyriform flaps from the groin, as in the last described case, and brought them together, in the manner beforementioned, by hare-lip pins, and interrupted suture, taking care that the edges of the lateral flaps were in apposition; I then drew the wounds, where flaps were taken from, together; I covered the flaps with carbolic dressing and cotton wadding. On the fourth day the twisted sutures were loosened and pins withdrawn; in eight weeks the wounds were perfectly healed, and I then proceeded to cover in the urethra. I made two lateral incisions, and dissected off the skin from the sides of the penis, and turning the cuticular surface towards the channelled urethra, I brought the edges together by means of interrupted suture, and passed in a bougie, oiled, and placed at its extremity charpie, so that no urine could possibly get to the cut surfaces; the urine escaped through the small opening left at the pubic portion of the penis. As soon as this was healed, I turned two flaps from the scrotum, covering over the remainder of the channel which was open, and joining their edges to the edges of the umbilical and lateral flaps. I then passed in a catheter, and kept it in the bladder till perfect union was established, keeping at the same time a light pad and bandage over the flap which covered in the bladder. This, the third part of the operation, finished the cure, which was complete, and everything that was to be desired. During the progress of the case the patient suffered distress and inconvenience from erection of the penis. Bromide of potassium, camphor, and belladonna afforded him relief. The deformities I have alluded to are more common than is generally thought, and not unfrequently the sufferers have lived beyond the allotted time of men, cases are recorded at the age of 75. The malformations are said to be most common in males, yet numerous cases are recorded in females, and recorded where women suffering from extroversion of the bladder have become pregnant (Huxham Bonnet, *Philos. Trans.*, vol. 23), and yet it is within a comparatively recent date that these deformities were even attempted to be remedied, and the sufferers from these dire conditions lived for the most part secluded, apart from, and shunned by mankind. For further operative accounts see Nélaton, Dupuytren, Ayres, Wood Richard, Simon, Pancoast.

I shall now relate the results of my experiments, made chiefly on the first case, that of Cecelia E. I was materially assisted in the carrying out of these experiments by my knowledge of Mr. Erichsen's observations. The quantity of urine passed was very equal, there being scarcely any appreciable difference, each ureter let fall a drop about four times in the minute; this, with the drop of the opposite side, joined. In the female case the ureters dropped very equally; in the male case the right dropped more frequently. In neither case did the ureters act at the same time; the urine dropped faster when standing than reclining, and on suddenly rising would flow continuously from half a drachm to a drachm; the urine in both cases was acid, in the female more so than the male. The mean of the specific gravity in the female case, from eight observations, was 1·015; in the male, from six observations, 1 020. Some of the substances I experimented with were prussiate of potash, the bicarbonate of soda, bicarbonate of potash, nitro-muriatic acid, benzoic acid, compound spirits of juniper, carbolic acid, triticum repens, uva ursi, senega, matico, pareira brava. One or two of these had been already used by Mr. Erichsen, my results were somewhat different. The first experiment was made with prussiate of potash, 3½ hours after the morning meal, at which she took an egg, tea, and bread; 15 grains of prussiate of potash in 3 ounces of water was drunk, in 7 minutes the salt appeared in the urine. The second experiment I made with this salt was 5 hours after a similar meal; 30 grains were taken, in 4½ minutes the salt could be detected. The next experiment was made 9½ hours after partaking of milk and bread, 35 grains were taken. The salt was detected in 1 minute and 35 seconds. The fourth experiment was made 20 minutes after a meal, at which was taken mutton chop, bread, porter half-a-pint. Thirty-five grains of the salt was administered; the salt could not be detected for 22 minutes. The next class of experiments was for the purpose of testing what time it would take to render the urine alkaline, and when alkaline, again acid. With this intention I gave her a drachm of liquor potassæ in a small cup of beef-tea two hours after a meal of chop, porter, and bread. The urine was alkaline in 3 minutes, tested with turmeric paper, and remained alkaline for 3 hours. I next gave her bicarbonate of soda, ℥ij, saturated with lemon juice, 4 hours after a meal of milk and bread. The urine was rendered alkaline in 2½ minutes, and remained so for 3 days. There was not any increase in the rapidity of the urine from the ureters. The next time I gave bicarbonate of potash, ℥ij., with orange-water, 3 hours after a meal of bread, butter, egg, and tea; the urine was alkaline in 11 minutes. Producing the same experiment after the same kind of meal, and administering the same quantity of potash 20 minutes after the meal, the urine was not alkaline for 45½ minutes. In the first instance it remained alkaline for 4 days; in the latter, for 2 days and about 7 hours. I again rendered the urine alkaline, and administered 20-drop doses of the nitro-muriatic acid dilute, every 5 minutes, till the urine became acid. The patient took 1 drachm and 40 minims; in 58 minutes the urine was acid. She had been 1 hour and 5 minutes after a meal of eggs, bread, and milk. I again rendered the urine alkaline, and 3½ hours after a meal of mutton, bread, and porter, gave 30 grains of benzoic acid; the urine was slightly acid in 15 minutes (I do not consider this experiment was satisfactory). I gave this patient grain doses of carbolic acid; after she had taken 10 doses, the urine had a tar odour, and was darker in colour. I put 6 ounces of saturated solution of carbolic acid into 4 gallons of water (warm); the male patient bathed his feet in this for 50 minutes, the urine became darker in colour, and smelled strongly of carbolic acid. I was anxious to test the absorbing power of the mucous surface of the bladder, believing that the bladder absorbed like other mucous surfaces, if only cleansed before hand. Although stated by many eminent writers, amongst whom is Sir Henry Thompson, to have no absorbing power, and that one need not be afraid of the quantity of anodynes introduced into the bladder. I washed over the surface of the female's bladder with tepid water, rubbed up 20 minims of the tincture of iodine with lard, and spread it over the superior portion of the membrane of the bladder. In three minutes iodine could be detected in the urine, and in 5 minutes it was palpably plain to the starch test. I placed the same in her vagina on another occasion, and in 8½ minutes iodine could be detected. I have on more than one occasion, placed morphia on the mucous surface of the bladder on both these patients, and produced sleep, and not only in these patients have I found a narcotic effect by morphia placed

on the mucous surface of the bladder when cleansed. I will quote one other, the case of a young married woman whom I endoscoped; Mr. Tufnell was present. She suffered severe pain from ulceration of the bladder, and having touched the ulcers with nitrate of silver, I placed a grain of morphia in her bladder; she was asleep in 18 minutes, and slept for four hours. I have merely now to state the drugs which I have found act most beneficially on bladder mucous as before stated. I have tried triticum repens, uva ursi, pareira brava, senega, matico, the balsams and various other drugs. Triticum repens I have not found of the slightest value in the removal of bladder mucus, it has a soothing effect, that in my opinion is its only property; it is described by James in his Medical Dict., 1743, as effectual against the gripes, difficulty of urine, ulcers of the bladder, and breaks the stone. I have used it in cases of lithotomy and lithotrity, and have not found it produce any better effects than barley water would. It does not seem to me to have any special influence on the genito-urinary tract. The medicines which had the most marked effect on the bladder mucous, in the cases I had operated on and others I had treated, were buchu and pareira brava; senega I also found useful. I could relate from my notes before me, as I write this, many cases of bladder mucous, how treated—the results, &c.—were it not I feel I have trespassed too long on the Society already. One interesting case I will briefly state: it was that of a gentleman on whom I operated for several urethral perineal fistulæ. Mr. Butcher, Mr. Tufnell, Dr. Benson, and Dr. Harley were present. In this case I eventually closed the last unhealed opening of the urethra by passing a pin from one side to the other, approximating the edges by a figure of-8-suture. I was obliged to keep in a catheter for twenty-seven days; he had much ropy mucus; in truth, it was as excessive as one suffering from an aggravated attack of chronic catarrh. I gave him pareira brava, and washed out his bladder with sulpho-carbolate of zinc, as is my plan in these cases; he was relieved of his distress and mucus, and I was enabled to retain the catheter in his bladder till I believed it might safely be withdrawn. I will not sum up the valuable deductions to be drawn from this paper, they are evident to every practical and scientific surgeon, and merely add that the greatest rapidity with which I could get water to flow from the ureter was at the rate of seventeen drops per minute, when the patient was taking a diuretic, the chief ingredient being compound spirit of juniper.

Clinical Records.

CONGENITAL DISPLACEMENT OF BOTH LENSES IN SIX MEMBERS OF A FAMILY.

Under the care of Mr. WORDSWORTH.

AT the meeting of the Medical Society of London, held on Monday, January 14, Mr. Wordsworth exhibited six persons belonging to one family who are all affected by congenital displacement of both crystalline lenses.

They consist of Mrs. H., her two sons, and their three children. A third son of Mrs. H., who is now in New Zealand, was examined many years since, and his case described in the first volume of the Royal London Ophthalmic Hospital Reports by Mr. Dixon. In addition, Mrs. H. states that her own father, his youngest brother, and her grandfather were all similarly affected. If this be so, there is a series of *ten* cases occurring in *five* successive generations.

They all complain of being short-sighted, and on close examination by oblique illumination, and when viewed by the ophthalmoscope, the crystalline lens in each eye is seen to be displaced, and its edge visible in the pupil.

For distant vision they look through that part of the pupil in which the crystalline is absent, and for near objects through the crystalline itself.

The family recognised the defect in all who are subject to it, and in those they considered exempt, the examination confirmed their opinion.

The annexed tabular statement, made by Dr. Morton, clinical assistant at the Moorfields Hospital, fully shows the particulars of these very interesting cases:—

Mrs. H., æt. 59. Displacement: R. E. upwards and inwards; L. E., do. Irides, light brown; lenses becoming opaque. Vision: 20-200th, scarcely, and J. 1. at 8 secs.; after atropine, with $\frac{1}{4}$ = 20-50th; after atropine, and with $\frac{1}{2}$ = J. 1. at 6 secs.

George H., æt. 37. R. E., inwards; L. E., inwards and slightly downwards- Irides, grey-blue. Vision: R. E. = 20-200th, nearly, and J. 19; with 1-20th = 20-70th; with $\frac{1}{3}$ = J. 12. at 6 secs.: L. E., 20-200th, and J. 1. at 1$\frac{1}{2}$ secs.; with 1-14th = 20-50th, and with $\frac{1}{3}$ = J. 1. at 5 secs.

William H., æt. 35. R. E., upwards and inwards; L. E., inwards. Irides, brown. Vision: R. E. = 20-200th, and J. 1. at 2 secs.; with 1-3$\frac{1}{2}$rd = 20-50th, and J. 1. at 8 secs.: L. E. = not 20-200th, J. 1. at 2 secs.; with $\frac{1}{2}$ = 20-100th; with 1-3$\frac{1}{2}$rd = 20-50th, and J. 1. at 5$\frac{1}{2}$ secs.

Maud H., æt. 10. R. E., inwards; L. E., do. Irides, grey. Vision: R. and L. = 20-200th, and J. 1. at 2 secs.; after atropine, with 1-12th = 20-200th, and with $\frac{1}{2}$ = J. 1. at 4 secs.

Alfred H., æt. 5. R. E., upwards; L. E., upwards and inwards. Irides, grey. Vision not proved.

George H., æt. 7. R. E., upwards and outwards; L. E., upwards and inwards. Irides, brown. Vision not proved.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE Fourth Meeting of the session was held on Friday evening, January 18, 1878; the Vice-President of the College, Mr. P. C. SMYLY, in the Chair.

The adjourned discussion on Mr. W. I. WHEELER's paper on

DEFORMITIES OF THE BLADDER, AND OPERATIONS THEREFOR; AND EXPERIMENTS TO TEST THE LENGTH OF THE INTERVALS BETWEEN THE ABSORPTION OF MEDICINES AND THEIR EXCRETION BY THE KIDNEYS; AS WELL AS EXPERIMENTS TO TEST THE INFLUENCE OF CERTAIN DRUGS ON THE SECRETION OF BLADDER MUCUS.

which will be found at page 106.

The VICE-PRESIDENT stated that the President had suggested to him that it would be well if Dr. Wheeler gave a short *résumé* of the paper he had read at the previous meeting of the Society, so as to more satisfactorily enable the meeting to commence the discussion. Of course it lay entirely with the meeting whether they wished such a course to be adopted, and the right of first speaking in the discussion lay with Mr. Rawdon Macnamara.

The motion as to the desirableness of Mr. Wheeler being asked to give a *résumé* of his paper having been put and unanjmously carried,

Mr. WHEELER gave a brief outline of the paper.

Professor RAWDON MACNAMARA said that on the last occasion he had had the privilege of moving the adjournment of the debate upon the most important paper of Mr. Wheeler's, because otherwise he did not think that adequate justice would be done to so important a communication. A vast number of subjects was opened up in the paper, and they would all, he dared say, in the course of the discussion approach them from their own standpoint. For instance, some might approach it from an etiological standpoint, and others from an embryological point of view; others might approach it from a variety of standpoints. But in consequence of some of Mr. Wheeler's experiments somewhat resembling some experiments he (Mr. Macnamara) made some years ago, and to which allusion had been made by the reader of the paper, he thought it as well to ask for the adjournment of the discussion, and he would now apply himself to that portion of the subject upon which he had contributed some facts. Now the case of Mr. Wheeler's was a remarkable one. It seemed one of the simplest things in the world to ascertain the rapidity with which medicines were eliminated by the urinary organs. *A priori*, anyone could take any patient and effect such experiments.

But it was not so easy to do so at all. In the first place, they wanted to get the secretion minute by minute, when the medicine was absorbed and carried into the urinary bladder. It was not so easy to get a patient, as it were, to make water at word of command. That was an exceedingly difficult thing. It was, however, his good fortune to get hold of a patient who had that rare gift, for when he held a vessel before him he would make water, and when he told the patient to stop he did stop, exactly at the moment he was told to stop. That was a very remarkable fact connected with that patient, who was suffering from hydrocele, and on whom he (Mr. Macnamara) performed the radical cure. It happened that upon the morning when he made his experiments, Dr. Haughton came up to the Meath Hospital, and thus the experiment was immortalised because it was quoted in Dr. Haughton's work on "Animal Mechanics," a work that would live when most of us had passed away. He would now read the words in which Dr. Haughton described the experiment. "The time occupied by absorption, circulation, and secretion combined, may be set down at less than four minutes, as appears from the following interesting experiment devised by Professor Macnamara of the Royal College of Surgeons in Ireland, at which I had an opportunity of assisting. An old soldier, a patient of the Meath Hospital, suffering from hydrocele, was trained by us to urinate at the word of command, at intervals of one minute, into a succession of of test tubes. When his training had been completed by a few days' instruction, the sac of the hydrocele was emptied, and injected with two drachms of tincture of iodine. The patient then urinated, at intervals of one minute, into the test tubes previously prepared, commencing at one minute after the injection. The fourth test tube responded faintly to the starch test for iodine, and the fifth and subsequent tubes showed its presence very distinctly. From this experiment, it is evident that the entire process — viz., absorption by the tunica vaginalis; transmission by the lymphatics and capillary veins to the heart; retransmission by the renal arteries to kidneys; secretion of urine, and its transmission to the bladder by the ureters—occupied less than four minutes, or about five times the entire time required for the circulation of the blood." There was very little merit attaching to that experiment, beyond that which was to be attributed to the patient; for it was very easy with such a patient to make the experiment. In all the cases of Mr. Wheeler, as far as he (Mr. Macnamara) remembered, the ureters opened exactly on the surface, and he had each time to perform the experiment on the urine as it was delivered, without its being required to be delivered into the bladder. Now he considered that that was a fact that should, in the course of the discussion, be held in recollection, because, having some experience in the treatment of these affections, he confessed he was surprised at the facility and length of time with which the urine was alkaline. Now he must say that it sometimes came to his lot to treat cases where he would be very anxious to make the urine alkaline, and the result of his experiments was that that was not so easily effected as it appeared to have been in Mr. Wheeler's cases. He (Mr. Macnamara) found it much more easy to make the urine acid than alkaline; but they could readily understand that. The great probability was that the explanation of those cases was that it was going on in a subject whose kidneys were distinctly healthy, and it was also going on in a subject where the urine was delivered without having reached the bladder. Probably that might be some explanation of Mr. Wheeler's case. It was an interesting fact, after all. He was sorry that Mr. Wheeler's experiments were not conducted on a still more extended scale, for he thought Mr. Wheeler had had an opportunity of establishing some very important facts in connection with the absorption of medicines. For instance—he (Mr. Macnamara) did not know whether Mr. Wheeler would have considered it right to do so or not—he should have liked to see what would be the result of the administration of mercury in such a case, and its excretion by the kidneys. It would have thrown a great deal of light on a question which was at this moment *sub judice*. The experiments which Mr. Wheeler had instituted seemed to him (the speaker) to have their principal value in pointing out, first, the rapidity with which absorption was effected in connection with medicines; and the second important observation to be deduced from them was, he thought, the power of certain medicines in producing alkaline reaction in urinary secretion. He must congratulate Mr. Wheeler on the immense amount of research he had displayed in his paper, the great amount of instruction it contained, and the manifest pleasure with which every one listened to it; and he (Mr. Macnamara) was sure that he was but expressing the sense of the meeting when he said how gratified they were to find one of their members contribute to their proceedings so important a paper as that which they had had the good fortune to hear on the occasion of their last meeting.

Dr. MAPOTHER said that, as he purposed addressing himself to the same view of the subject as Mr. Macnamara had —viz., the physiological action of medicines—in alluding to the very interesting series of experiments made by the reader of the paper, it might be more convenient that he should speak now. He thought the most interesting and important part of Mr. Wheeler's very comprehensive paper was that detailing the rate of passage of various chemical agents from the stomach to the bladder. The results had verified those of Erichsen, when lecturer on physiology in Westminster Hospital, in 1845. Ferro-cyanide of potassium passed in one minute if taken eleven hours after food, and in thirty-nine when given after a full meal. The patient was not very tolerant of physiological trials; but Mr. Wheeler's should have been more so, for amendment by surgical procedure was promised, and afterwards carried out. The rapid passage of certain substances, and the tardy appearance of others, could be explained by their crystalloid or colloid nature—terms afterwards applied by Graham. The long continued alkalinity of the urine after the dose of alkaline salts could not have depended upon their neutralising the acid of the urine. In one of Erichsen's experiments, that fluid was alkaline for six days after the taking of 120 grains of bicarbonate of soda; during that time the acidity of the urine would have probably averaged that of 270 grains of oxalic acid. If such grand opportunities for physiological and therapeutical research should again occur, quantitative analyses of the urine at regular periods after the ingestion of saline and other drugs of more complex nature, would be very desirable, especially if the kinds of foods and times when taken were precisely noted. The practitioner would thus be guided as to the most suitable times for administering various medicines. If Mr. Wheeler had sought for the iodide in the tears or saliva, instead of in the urine, which it might possibly have reached directly, more conclusive evidence would have been given regarding the absorbing power of the mucous surface of the bladder. With Professor Macnamara, he thought the paper of the highest possible interest and value.

Mr. B. WILLS RICHARDSON said: With regard to the first part of Mr. Wheeler's paper, I shall make no comment, for I have nothing new to say on embryology and, in the second place, because the subject, so cleverly epitomised by him, is fully described in many standard works on physiology. There are some points, however, in the second portion of his communication that appear to me to be open to comment. I allude to those bearing upon the absorbing power of the bladder. The Society may be again reminded that a few of Mr. Wheeler's experiments were performed with the object of disproving the accuracy of Sir Henry Thompson's opinion regarding the non-absorbing power of the mucous membrane of the bladder. I had better, however, before entering into Mr. Wheeler's experiments, give the observations of Sir Henry Thompson as they appear in the last edition of his Clinical Lectures. They are as follows:—"The mucous membrane of the bladder," he states, "appears to have no absorbing power, unlike the neighbouring tissue which lines the rectum;" and in a note on the same page he remarks, that "some one thought proper to question, in one of the journals, the accuracy of this statement, relative to the effect of narcotic injections into the bladder, and even to caution my readers against relying upon me too implicitly. It might have seemed otherwise almost unnecessary to say, that this statement was the result of very numerous experiments and observations; and its object was to show that such injections were of small service, and, therefore, not to be recommended. My only reply to the critic was to inject *four drachms* of liq. opii sed. into the bladder of a patient with chronic cystitis, in one of my wards in University College Hospital, on four separate occasions in presence of the students, who verified for themselves the absence of any sign of the presence of opium in the system. Subsequently, a dose (by mouth) of twenty minims, produced them almost notably." I now come to Mr. Wheeler's observations. "I was anxious (he

says), to test the absorbing power of the mucous surface of the bladder, believing that the bladder absorbed like other mucous surfaces, if only cleaned beforehand, although stated by many eminent writers, amongst whom is Sir Henry Thompson, to have no absorbing power, and that one need not be afraid of the quantity of anodynes introduced into the bladder." Mr. Wheeler proceeds :—"I washed over the surface of the female's bladder, [he is speaking of the extroverted bladder] "with tepid water, rubbed up twenty minims of the tincture of iodine with lard, and spread it over the superior portion of the mucous membrane of the bladder. In three minutes iodine could be detected in the urine, and in five minutes it was palpably plain to the starch test. I placed the same in her vagina on another occasion, and in eight and a-half minutes iodine could be detected. I have on more than one occasion placed morphia on the mucous surface of the bladder of both these patients" —one a male, the other a female—"and produced sleep ; and not only in these patients, I have found a narcotic effect by morphia placed on the mucous surface of the bladder when cleansed." It would be satisfactory were Mr. Wheeler to mention the intervals that elapsed between these experiments and the occurrence of sleep. It appears to me that the iodine experiment was a very fallacious one, and I think, with Dr. Mapother, it is open to criticism, because the iodine could have readily descended to the ureters, and mixed with the urine in which it was detected. Let me again remind the Society that this was an 'extroverted bladder,' or piece of bladder, the exposed surface of which Mr. Wheeler assumes to be analogous in function with the surface of the normally-formed closed reservoir. He goes on to say :—"I will quote one other, the case of a young married woman whom I endoscoped—Mr. Tufnell was present—she suffered severe pain from ulceration of the bladder, and having touched the ulcer with nitrate of silver, I placed a grain of morphia in her bladder ; she was asleep in eighteen minutes, and slept for five hours." It would be advisable were Mr. Wheeler to tell us the length of time occupied with the endoscopic examination? The postponement of the discussion to this evening enabled me to communicate with Sir Henry Thompson on this interesting question chiefly to ascertain whether he had modified his opinion, on the non-absorbing property of the closed vesical reservoir, and at the same time to ascertain if he had any experience of experiments on the extroverted organ. To my questions thereon, he kindly sent me the following replies :—He tells me that he has no experience of experiments on the extroverted bladder, and he agrees with me in thinking that the condition of an exposed mucous membrane is not in the least analogous to the lining of a reservoir, with which the air never comes in contact. He has experimented only on ordinary well-formed bladders usually with some chronic cystitis present. He should never dream of applying morphia, in the expectation of furthering this inquiry, to an ulcerated surface. He should expect such a surface absorbent, of course ; and he considers that there is no kind of analogy between the action of a salt laid on a raw vascular surface and on the unbroken lining of the bladder. Break the surface of the mucous membrane or of the skin, and you may find absorption active enough, as in the case of vaccine and syphilitic viruses, both of which are handled with impunity, but applied to the slightest breach of surface, are absorbed. Nothing that you have named as an illustrative experiment (Mr. Wheeler's experiment) bears on the subject in the slightest degree. But he has several times, in University College Hospital, in presence of the pupils, and once in presence of a journal reporter, who watched the result and published it, injected a drachm of liquor opii into a bladder slightly inflamed only, without the smallest effect on the system. He was led, many years ago, to the result in consequence of injecting bladders, which were the cause of great suffering, with opiates, in the hope to allay pain and affect the system, and without effect, which surprised him. No doubt that the mucous lining of the bladder is that of a *non-absorbing* reservoir, wholly differing from that which lines any portion of the intestinal tube, which is throughout, more or less, *an absorbing canal.* Thinking it desirable to have an explanation of Sir Henry Thompson's observation as to the impunity with which the syphilitic virus might be handled, he also favoured me with a reply to a letter in which I asked for such. He says that his "belief has long been that syphilitic infection never takes place, except when there is some breach of surface. Why should it? When the male organ is erect, the minutest crack in the skin round the prominent ridge of the corona is so very likely to take place. The mechanism of the act is the best possible one can conceive for getting a microscopic crack inoculated, if a sore, or its secretions be in the way. The favourite situation for sores indicates this mode of inoculation ; and it is never by the finger that syphilis enters the system, unless there is a crack or sore there ; and yet, as every man knows, the finger—take the world round—is, perhaps, quite as much exposed as the penis, only the skin is not so tender on the finger, and is not liable to the *great and sudden extension which so much favours the cracking* he refers to. If handling syphilitic or any other animal poison risked infection, how many of us would escape? As it is, only an occasional accoucheur who gets it, and he always had some sore or crack on his finger —"at least," he "always" hears "that it has been so. Such," he concludes, "have long been" his "views, and," he thinks, "a little reflection will show, at least, there is some probability of their accuracy." These are Sir Henry Thompson's opinions ; and in conclusion I may observe that, some years ago, I frequently injected 20 grains of extract of belladonna into chronically-inflamed bladders, and eventually relinquished the use of the drug, not seeing any resulting benefit therefrom. At all events, in none of the cases were the specific effects of belladonna on the system observed ; whereas, I have known three grains of this extract given by the rectum to produce most alarming symptoms.

Dr. O'LEARY regretted that he had not heard the paper read, but from what he had heard in the discussion of the teaching of the opinions of Sir Henry Thompson, he (Dr. O'Leary), thought the conclusions derived from them might be somewhat fallacious. In the first place, he thought that in all Sir Henry Thompson's cases, the bladder was not a healthy surface ; it was a diseased surface. It was a surface labouring under chronic inflammation, of inflammation of some sort ; it was not in a physiological, but it was in a pathological state at that time, so as to arrest its function, and also to cause effusion from its surface, throwing off all its superficial cells and secreting mucus on the surface, on an impermeable surface, and causing a physical obstacle to absorption. No one would deny that in the case of the mucous membrane of the stomach, it was an absorbing surface, and that it did absorb, they knew. The very old experiments quoted by Dr. Mapother, were known to every student, and they knew well that if a membrane be in the slightest way inflamed, artificial substances would not be absorbed. They also knew that when ordinary food was applied to the surface of the stomach, the stomach absolutely refused to absorb that food, and even ordinary albumen would not be absorbed as a consequence, simply because it was not up to the physiological standard. It was a general complaint that terms were too often used generally in speaking of the bladder as an absorbing surface, but that might be modified as a consequence, according to the condition in which the organ was. If the bladder was inflamed, it differed essentially from a bladder in a state of health. The bladder or any other mucous surface was different from the stomach as to its capability of absorbing, and therefore, he would say that that showed that the conclusions that Dr Richardson had quoted, and had also stated to be the views of Sir Henry Thompson, were fallacious as they were not applicable to the case of a healthy bladder, for the simple reason that every membrane—and this was a matter of physical fact—if it be a simple permeable membrane, and two fluids of different specific gravities on either side of that membrane, as a physical necessity they would interchange each other. There was but one single exception to that as a physical law, and it was that where they had glands commencing by cæcal extremities lined by glandular epithelium, and secreting various fluids, such as saliva, pancreatic and liver, and the gastric juices. Here these laws did not operate, the membrane in these cases being differentiated, passing according to the law of Von Baer, from the general to the special. Such alone prevented the physical law of osmosis.

Mr. B. W. RICHARDSON : Would Dr. O'Leary speak to the question? How does he explain the supposed absorption by the bladder in Mr. Wheeler's cases when it was inflamed?

Dr. O'LEARY understood Mr. Richardson to say that the surface of the bladder in the case of Dr. Wheeler's was an ulcerated surface, and he, therefore, thought Mr. Richardson disposed of that at once. He (Dr. O'Leary) was referring to

the misapplication of that which arose under a pathological condition to that which should follow as a physiological one. Mr. Richardson mentioned as an objection to Mr. Wheeler's case, that the bladder was ulcerated, that in fact it was an ulcerated surface, and therefore, he (Dr. O'Leary) did not touch on that. It was undeniable that an ulcerated surface could absorb.

Mr. E. HAMILTON wished to say a few words upon the interesting communication of Mr. Wheeler's, principally upon its physiological aspect. He (Mr. Hamilton) could hardly agree with everything put forward by his friend, Dr. O'Leary, that this law of endosmose was universal in living bodies. He (Mr. Hamilton) thought there was something in vital force, whatever it might be which limited and checked that physical law of endosmose. How was it that the little red cells of blood would maintain their potash salts floating in a bath of soda salts? That was but a simple example; there were many others. Now he did not consider that in Mr. Wheeler's cases the mucous membrane of the bladder was in anything like a healthy state. It was not a natural condition for the mucous membrane of the bladder to be exposed to the air, and therefore he was satisfied as a physiologist, that its exposure to the air would make marked changes in the mucous membrane, and alter the membrane altogether from its natural condition. He was sure, therefore, that in Mr. Wheeler's cases there were marked changes in the mucous membrane, which might account for the violation of natural laws, and it might be an explanation of Mr. Wheeler's cases that the membrane had become an absorbent surface. But he would accept Mr. Wheeler's facts sooner than a thousand theories. Still he thought they must look for every means of explaining the alterations in what appeared to be the absolute laws of nature. There was coming into their hands very much, and it would come into the hands of the student, because it was an exceedingly good book, a modern Treatise on Physiology in which this subject was very ably entered upon and discussed, and in which, indeed, a very marked dogma, a distinct positive assertion is made. If Mr. Wheeler's statements be true, and cannot be explained by the alteration of mucous membrane by exposure to the air, it would give a complete upset to the statements put forth by this writer; he referred to the Physiological Lectures by Dr. Kuss, professor of physiology at Strasburg, in which the following statement was made:—

"The vesical epithelium," says he, "is of the pavement or stratified form, but its superficial cellular elements are remarkable for their irregularity and oddity of shape. From the physiological point of view, this epithelium is remarkable for its impermeability; it absolutely opposes the transmission of liquids. A solution of belladonna may be kept in a perfectly healthy bladder for a long time, without risk of poisoning from atropine; so, also, may solutions of opium, without danger of opium poisoning. But if the epithelium is diseased, absorption immediately occurs; and as an example, when dilute alcohol is injected into the bladder in which there exists catarrhal inflammation, symptoms of alcoholic intoxication are manifested. The vesical epithelium, even for some hours after death, preserves its vitality, and consequently its impermeability. If ferro-cyanide of potassium be injected through a tube, thus preventing contact with the urethral mucous surface, into the bladder of an animal which has just been killed, then the bladder be exposed, and a ferric salt placed upon the outside of its walls, no Prussian-blue will be seen. This experiment shows that the two salts, which in contact would produce Prussian-blue, are separated by an impassable barrier, viz., the epithelium. Yet, if by means of a wire the epithelial coat on the inside of the bladder be scratched or destroyed at this point, Prussian-blue will be immediately formed. This opposition, then, to the passage of liquids results solely from the presence of the epithelium." If Dr. Kuss's experiments were correct, and if Mr. Wheeler's were also correct, they were placed in a dilemma, and for himself, he (Mr. Hamilton) said that the only explanation was that the mucous membrane had undergone a marked alteration, that its natural condition was completely changed, that it was almost converted into an absorbent membrane, and he thought with those very opposite statements that they must try and find some means of reconciling them.

Mr. WHEELER in reply, said that in the first place he had to express his regret that the discussion did not take place on the night he read his paper; and in the next place, he had to offer his best thanks to Professor Macnamara for the complimentary manner in which he had spoken of his endeavour to bring an interesting paper before the Society. With regard to the statement as to the small number of the experiments he had made, he assured the Society that notwithstanding the fact that they might appear small, they involved an immensity of labour. All the experiments that he made were not at all before the Society. The experiments which he made with carbolic acid, benzoic acid, and to see the time it took when the urine was rendered alkaline to make it acid again, had not been brought under the notice of the Society that night, but were detailed in his paper read on the previous night of meeting. He was aware of the interesting experiments of Mr. Macnamara as detailed in Dr. Haughton's book on Animal Mechanics, and was anxious that the reference to it in his (Mr. Wheeler's) paper should appear. With regard to what Dr. Mapother and Mr. Richardson had said as to the iodine test being fallacious, he (Mr. Wheeler) at once admitted that if it had been tested for in the saliva, the experiment would probably have been more satisfactory. He did not think his case and that of the cast exhibited by Mr. Richardson were analogous, inasmuch as the cast was that of a young boy from Houston's Collection in the Museum. In that case, there would be more than a quarter of an inch from the exposed bladder to the ureters, but in the case that he (Mr. Wheeler) experimented upon, and a drawing of which he now exhibited, there would be at least two inches from the ureters to the place where the iodine and lard was. Besides, the experiment proved that the vagina absorbed the iodine, and the same structure that formed the mucous membrane of the bladder formed the mucous membrane of the vagina. Mr. Wheeler now referred to a diagram which he had drawn on the board, showing that the splanchnopleure, or hypoblast, with inner layer of mesoblast, formed the mucous membrane of the bladder and vagina, and if one mucous membrane absorbed, there was no reason why the other should not. There was not any ulceration of the bladder on its surface in the case referred to. The only question which could arise, was the one put forward by Dr. Hamilton, whether the external air could influence its absorbing powers. If he mistook not, Professor Kuss stated that the mucous membrane of the vagina did not absorb. With regard to anodynes being injected into the bladder, he might state that the President of the College had mentioned in the course of conversation a case in the practice of Mr. Hutton, where belladonna was injected into the bladder, and the patient had the signs of poisoning by that drug. Whether that bladder was diseased or not, he could not say. Mr. Richardson had asked him the length of time it took him to endoscope the patient. It took him about three quarters of an hour; he did not make a note, but he believed that was the time. With regard to the length of time it took for the patient suffering from extroversion to come under the influence of morphia, was about 25 minutes, and previously she had been in the habit of taking morphia by the mouth. In conclusion, Mr. Wheeler said he was glad that the paper had elicited so important a discussion.

THE "MEDICAL PRESS" SPECIAL REPORT

ON

THE NATURE OF RABIES,

AND THOSE DISEASES RESEMBLING IT,

IN WHICH

HYDROPHOBIA IS A PROMINENT SYMPTOM

CHAPTER IX.—PREVENTIVE MEASURES.

SANITARY science has become one of the most important branches of human knowledge, and research. It aims at suppressing diseases entirely, by preventing the diffusion of the virulent elements, on which their maintenance and vitality depend, and preventive measures, if carried into operation with energy and circumspection, cannot but have a controlling power over the spread of rabies. The measures we recommend should have for their object not only the prevention of disastrous consequences to mankind from the presence of rabid dogs, but should also be based on humane and utilitarian principles so far as dogs and other animals are concerned. We may say that the veterinary police measures to be applied to this disease are founded on the consideration that,

though it *may* be developed spontaneously in the canine and feline species, and though this spontaneous development may be more or less averted by proper hygienic treatment of these animals in a domesticated state, yet that perhaps 999 in 1,000 cases are due to contagion alone, and that, therefore, the destruction of the contagious source or sources is of primary importance; also that rabies is not peculiar to any season, but may and does appear at all times of the year in a sporadic or epizöotic form. These measures in the general interest of the community should be adopted and rigorously enforced, and owners of dogs or other domestic animals should be compelled to attend to them.

Hygienic Treatment of Dogs.

No amount of reasonable care can be considered superfluous to preserve the health of domestic animals, and to protect them from disease and its results. Hence the hygiene of the dog is so important.

Animals should be provided with wholesome food, solid and liquid, and cleanliness cannot be too strictly enforced. Their kennels should be provided with fresh straw, fine shavings, or sawdust, and their supply of water should be unlimited.

Dogs should not be needlessly excited, abused, or maltreated. If it should happen that an excited dog bites anyone the person who excited it should be held guilty of a legal offence. This is in accordance with the Austrian law and the jurisprudence of our ancestors in this country—the Celts.

Dogs should be allowed exercise, and nothing can be more reprehensible than keeping them confined to houses for days together, or chaining them for weeks and months to a kennel. It is quite opposed to the animals' natural instincts. All quarrelsome and vicious dogs should be particularly taken care of by their owners, and neglect of precautions should bring the offender within the penal code. This is also in accordance with French law.

Diminish the Number of Useless Dogs.

In an economical point of view the diminution of the number of useless dogs is most desirable, and from a sanitary point of view is even more essential. Useless dogs are badly kept by poor people, and are allowed to run about dirty and diseased. They are a source of waste and insalubrity, as they absorb the already insufficient supply of oxygen in the miserable and badly-ventilated dwellings of their owners, and they consume a certain quantity of food that can ill be spared. Pleasure dogs kept by the richer classes are scarcely less a source of danger and extravagance, for they appear very predisposed to rabies, whilst the food they consume forms no inconsiderable item of expense.

If we calculate the number of dogs licensed, and add at least half that number as escaping the duty, and estimate the value of the food consumed at 1d. per day, we can form an approximate idea of the sum annually expended. Thus, in England and Scotland the number of licenses issued in 1877 was 1,063,967 (Mr. Cockell, Inland Revenue Office).

In France, in 1855, it was computed that there were 3,000,000 dogs, costing 18,000,000 fr. annually. In Austria the number of pleasure dogs is said to be 1,000,000, and the expense of their annual keep 3,000,000 gulden. This decrease may be effected in several ways, the chief of which are *taxation*, and the *capture* and, if need be, *destruction* of vagabond or stray dogs.

The evidence of other countries, as Baden and Copenhagen, establishes that the imposition of a tax upon dogs is generally very effective in diminishing their numbers, and the *higher the tax* and the more strictly it is imposed, so will the useless dogs become fewer.

A measure of this kind should be resorted to. It would be most effectual in ridding the country of a number of miserable and dangerous animals. But to be really efficient the tax should be *general and high*, exception being only made in favour of dogs that are useful, or whose services can be proved to be absolutely necessary, such as house and yard dogs, or those employed by shepherds, or to lead the blind about.

The tax should be highest for pleasure and sporting dogs, for whoever can afford to indulge in keeping such animals can also afford to pay a high tax. If, however, it can be shown that sporting dogs are necessary, then the impost might be reduced to that levied for useful animals.

Dogs and bitches should be equally taxed; puppies should be sold, not given away, and all that are not purchased should be destroyed.

As soon as they are weaned the tax should be demanded. The tax should be paid half-yearly. *Every dog should wear a collar, with a brass plate inscribed with the name and address of the owner, and stamped with a particular mark of the police or inland revenue authorities*, as a guarantee that the tax is paid, and for purpose of identification. This custom exists in Holland, and is very effectually carried out at Strasburg. At the latter place every owner must notify his possessing a dog to the police, who furnish him with a license, duly numbered and registered. This number, with the address of the owner, is inscribed on the collar, which every dog has to wear.

It would be well if in all towns and villages there was a dog census, or list of the dogs kept therein.

All stray dogs without the collar, or which have not the mark or their owner's name thereon, should be captured and sold or destroyed immediately or after a certain period. This period might be extended to three days, and if the animal be claimed by its owner a fine must be imposed and all expenses paid. At Strasburg the expenses amount to 15 fr., so that 15s. in England would not be an excessive fine.

Straying dogs may, even when furnished with a collar, under certain circumstances—as when rabies prevails—be seized by the police and conveyed to their owners, who shall pay all expenses.

This addressed and numbered collar is useful in the case of damage done by dogs, as everyone should be held responsible for the damage done by his dog, due to his negligence or imprudence. Bitches in rut should not be allowed to wander about at any time, whether with or without the collar, as they excite dogs and lead to quarrels.

Emasculation.

Neither experience nor observation at present justify recourse to this measure. It may be left to the discretion of dog owners.

Blunting the Teeth.

This operation has been proposed with the view of reducing the dog's jaws to the same condition as that of herbivorous creatures, whose bites are not so dangerous as those of the carnivora—so far, at least, as the inoculation of the rabid virus is concerned.

M. Bourrel, who has had a long experience of dogs and rabies, has proposed this measure, but it has never been carried into general practice.

Muzzling.

The use of the muzzle has become such a popular institution in nearly every country in which legislative measures for the prevention of injuries from dogs have been adopted, that any question as to the benefits conferred by it may be deemed superfluous by those who have not paid deep attention to the subject. The old muzzle has almost now disappeared, and we have only to consider the more modern and improved wire muzzle. The most varied opinions prevail in reference to its value. By some it has been deemed useless or worse, whilst others are satisfied that by the adoption of a properly-constructed muzzle the dangers resulting from rabies might be averted. The principal French authorities incline to the former opinion, while the German veterinarians appear to favour the second. We are inclined to the opinion that the muzzle should only be worn on special occasions, as when rabies is prevalent in a locality, or when it has a tendency to assume an epizöotic form, or in the case of vicious dogs. We must not forget that this muzzle cannot be an efficient safeguard unless it is, as Mr Bouley says, rivetted to the dog's neck, as the manacle is to the foot of the galley-slave, and that night and day the animal should wear it, indoors as well as out-of-doors.

When the disease threatens to become prevalent, or, indeed, when there is reason to believe that a mad dog has bit several others, and these cannot be discovered, the use of the muzzle should be resorted to—not as a prophylactic, but as an adjuvant.

All dogs seen in the streets of towns, or in the country, without a muzzle should be seized by the police as suspicious animals.

This is one of the great advantages of employing the muzzle, for as it is stated by good authority that rabid animals escape from their houses unmuzzled, a dog so unprovided, especially when muzzling is in force, should be at once captured. In this opinion we are strengthened by the evidence of Fürstenburg, of Eldena, Prussia, and of Hering, Director of the Veterinary School at Stutgart.

To be beneficial it is obvious that the employment of the muzzle must be universal; but, at the same time, should the

disease be prevalent, the other necessary measures must not be relaxed; neither must the vigilance of dog owners be diminished, for it must be remembered that if a dog wearing a muzzle runs about without anyone in charge of it, it is possible that a mad dog may attack and bite it; the wounded animal then returns to its home, and the owner may know nothing of what has happened until all at once rabies appears quite unexpectedly.

A well-constructed muzzle is a protection so long as it is worn by the dog, but a bad muzzle is worse than useless, as it establishes a false security.

Dogs soon become accustomed to an easy, comfortable muzzle—that is, one in which they can always breathe and drink without hindrance. The nostrils of the dog are very narrow, and even under ordinary circumstances he cannot breathe so comfortably as many other animals when its mouth is forcibly closed.

When distressed by running the dog always respires with open mouth, and in warm weather the transpiration that takes place in this cavity from the throat, tongue, and inside the cheeks tends to keep the creature cool, and compensates for the almost total absence of this process by the skin. Therefore, the front portion of the muzzle should be sufficiently accomodating as to allow of the animal wearing it to open its mouth freely and widely. The muzzle patented by Grauhan is a good though not a very safe one in its present form. To make it perfectly secure, at the mouth there should be intermediate wires, from the circular transverse wire, near the eyes, to the vertical nose wire. The muzzle should fit the head properly, and, above all things, it should be securely fastened round the neck. The neck strap should be strong, and as tight as can be, compatible with the dog's comfort.

Quarantine.

The idea of completely extinguishing rabies by establishing a quarantine of several months' duration amongst dogs was based on the assumption that the disease is only maintained by contagion, and never arises *spontaneously*, and that, therefore, if these animals could be confined for a certain period without any intercourse or any chance of the contagium being transmitted from those that were infected at the commencement of the measure, the pestilence must inevitably die out.

The preventive scheme proposed by Bardsley rests upon the validity of the following propositions:—

1st. That the disease always originates in the canine species.

2nd. That it never arises in them spontaneously.

3rd. That the contagion, when received by them, never remains latent more than a few months.

Quarantine would, no doubt, be as effectual in stamping out rabies as in stamping out any purely contagious malady, were those propositions absolutely correct, and the measure completely and permanently enforced. But, unfortunately, the disease originates in other than the canine species, and in other creatures besides the dog, and, unfortunately, also, we are far from convinced that it never occurs *spontaneously*; on the contrary, though ready to admit that in the great majority of cases it is spread by contagion, there is evidence which tends to show that it may arise without this influence. Besides, this authority proposed only two months as the period which he considered long enough to afford every prospect of success, whereas it is a well established fact that the incubatory stage is frequently protracted to a much longer interval: indeed, he admits this when he adds "that it would undoubtedly be erring on the safe side if the time of quarantine should be extended to the very unusual period of *eight months*." It will be seen at once, by those who know anything of veterinary sanitary matters, that a strict quarantine for dogs for such a period, or even for the comparatively short space of two months, is absolutely impossible at present, and, perhaps, will always be so, and also that, supposing the disease to be confined to the dog species, and the quarantine to be religiously observed or rigorously enforced, other countries might not think fit to submit to the serious inconveniences arising from this measure, and consequently we should, in all probability, have the contagion introduced into the country again in a very brief space.

Public Instructions.

Dog owners, when they receive their tax-papers, should be provided with printed and easily-understood instructions as to the proper method of keeping their dogs healthy, and how to detect the symptoms of rabies. They would thus be informed of the preservative and sanitary police measures, which they should comply with in order to prevent the disease. All this might be printed on the back of the tax paper, which could in addition, be made a valuable means of arriving at certain important information, such as the sex, age, breed, of the licensed dogs. The most serious accidents have occurred through the ignorance of the public on simple matters connected with rabies. Such, then, are the general measures to be recommended with regard to the prevention of rabies at ordinary times and at all seasons, for our investigations have shown in the clearest and most positive manner that the disease is not peculiar to any particular period of the year, nor limited to any season, but may prevail at any time. Therefore, careful supervision should be extended to all dogs throughout the year, and not only during the "dog days"; and it is to this supervision and the possession of a general knowledge of the symptoms of the malady by everyone who keeps a dog that we must look for success in keeping down the contagion, and preventing the sacrifice of human and animal life through the effects of this disease.

We look, then, for improvement very much to education, and to the principle of personal responsibility of dog owners.

Fines and penalties would affect their pecuniary interests—unfortunately so much more powerful than those of a sanitary character—for they thus learn that, in the words of M. Bouley, "the fear of a diseased dog is not only the beginning of wisdom, but wisdom itself."

Measures to be adopted when Rabies has appeared.—Suspected Animals.

If, notwithstanding these measures, morbid or unusual symptoms appear in a dog, and particularly if cases of rabies have occurred in the vicinity shortly before, it should be carefully observed, and every precaution taken, as these may be premonitory symptoms of madness, which is contagious from its commencement.

The animal should therefore be constantly watched and kept apart from mankind and other animals, and in feeding or attending to it the greatest possible care should be taken that it does not bite anyone at this time. No children should be permitted to approach it, and all neglect of these precautions ought to be visited with severe punishment. If the morbid symptoms become more marked or more suspicious, if it is observed that the dog manifests any of the peculiarities proper to rabies, that it is dull and bad tempered, moves languidly from place to place, or seeks to go away, that its ordinary habits have changed, that it is hostile to people or animals, that it attempts to bite everything, then it is time to chain it up securely or keep it in such a way that no one can be injured by it. If the owner has not the means of affording sufficient security he should report the circumstance to the local police, under the penalty of criminal liability. Whoever knows of a dog, or any animal placed under exposed conditions, must also report to the police under a similar criminal responsibility. The Austrian penal code is very strict on this point, and for an infraction of the law renders the culprit liable to incarceration, from three days to three months. If the death of a man has been the consequence of neglect, the penalty is from six months to a year's close imprisonment. Should a dog in a suspicious state escape from home, the local authorities should give warning to the inhabitants, and medical men and veterinary surgeons should assist in instructing the public on the symptoms of the disease both at its commencement and when it is fully developed.

If the owner is aware that the sick or supected creature has been bitten by a rabid animal, his precautions should be still more strict, and if the animal developes more serious symptoms, the services of an expert should be secured, the police authorities informed, and if there is any doubt, the animal should be at once sacrificed.

Mad Animals, or Those Wounded by Them.

The following measures should be rigorously enforced:—

1. That dogs suspected of or attacked by rabies, or one that has been bitten by a rabid animal, should not be killed at once and buried, unless it is positively ascertained that no person has been wounded by it.

2. If a person has been bitten by an animal really affected with rabies, or suspected to be affected with that disease, it should only be killed if the malady is unmistakably present.

CASE CL.— ——.

Remarks.—That the malady may be transmitted by the virus from a dead animal, has quite recently received another

illustration in the case of M. Moreau, a veterinary surgeon of La Capelle, Aisne, France. In last July, M. Moreau was sent for to Lerzy, to examine the body of a dog which was supposed to have been affected with rabies; and he did so, forgetting that he had a slight abrasion on one of his hands. In the last week of October he began to exhibit the early symptoms of hydrophobia, which he soon recognised. Dr. Mennesson attended him during the course of the disease, but no remedies or appliances afforded relief. The unfortunate man retained consciousness until the last, and his self-possession never deserted him. He implored his attendants not to inspire his breath, and shortly before he died he bade farewell to his wife and child.

Reference.—*Veterinary Journal*, Dec., 1877.

CASE CLI.— ——, male, æt. 45, bitten on the finger by his own rabid dog.

Result and Time of Attack.—Recovery.

Remarks.—This case was reported by Dr. Watson, of Jersey City, in the *American Journal of Medical Science*, July, 1876, and regarded by him and Professor Austin Flint as a pure case of rabies. The dog was mad, and a servant girl who was bitten at the same time, and by the same animal, died from unmistakable rabies. Curara was employed. The doses were augmented from 1-16th grain, 1-9th grain, to 1-6th grain, when after the third injection, the unfavourable symptoms subsided.

WEDNESDAY, FEBRUARY 6, 1878.

PROSTITUTION, AND THE GENEVA CONGRESS.—II.

IN a previous article on this subject we made a few general remarks on the international movement that is now going on with the view of "abolishing prostitution, especially regarded as an institution tolerated by government." In order to give as complete a scope as possible to the study of the question, and in order to inquire into the remote causes which foster this evil, and the most effective means of combating them, the Congress, recently held at Geneva, distributed its labours into the five sections of Hygiene, Morality, Social Economy, Preventive and Reformatory Work, and Legislation. The debates on these sections led to the series of resolutions to which we now propose to draw the attention of the reader.

With regard to the section of Hygiene, we cannot congratulate the Congress on the practical wisdom or comprehensiveness of the resolutions it has passed under that head. Hygiene is a science, and a department of political economy, which deals with the prevention of disease, and of the conditions of disease. Everyone will admit that prostitution is one of those conditions; but in the resolutions before us we fail to see any good and practical suggestions for the prevention of either the evil itself, or of the manifold disorders arising from it. That "self-control" is indispensable to the health of the individual and communities; that prostitution is a fundamental violation of the laws of health; that the true function of public hygiene is to develope all the conditions which conduce to public health; that all systems of *Police des Mœurs* are to be condemned; and that all the obstacles to the treatment of venereal maladies in general hospitals should be removed—these abstract principles, and negative opinions, are all that the Congress has to offer as a result of its discussion of so important a subject as that of prostitution from a hygienic point of view. Nor are these resolutions, meagre and impracticable as they are, such as every sanitarian will, in principle, readily endorse. Self-control in the relations between the sexes, may be, abstractly considered, an indispensable basis of individual and public health, but as man and society are at present constituted, it is mere Utopianism to suppose that the inculcation of such a principle can be made an indispensable basis for the attainment of the object the Federation has in view. Even could the principle be strictly and absolutely carried out, it might even, in numberless instances, be detrimental to that healthy tone of mind and body which the moralist, the politician, and the physician, alike endeavour to secure. Self-control between the sexes would too often end in self-abuse; and even if there was a total abnegation of all kinds of venereal indulgencies, we might still have, in many cases, that disturbance of the mental, intellectual, or emotional faculties, or that derangement of the whole nervous system, which we often see associated with great functional activity, but enforced disuse, of the generative organs. But the truth is, that the general observance of perfect self-control is most impracticable in that very condition of Society in which it is the most desirable. In the more primitive states of Society, among nomadic tribes, among savages, and where the population is thin and scattered, where the females are in a great minority, and where the lives of whole tribes of men are spent in constant warfare or in the pursuit of game, under such circumstances, self-control is more common or more practicable. If there is one thing more than another that subdues the venereal appetite, that "abates the sexual sting," and even robs the sexual organs of their customary vigour, it is protracted exercise, laborious occupation, and life in the open air.

"Cedit amor rebus; res agetutus eris,"

and, as old Burton reminds us, Minerva, Diana, and Vesta were never enamoured at all, because they wer never idle. But very different is the phase of existence

presented by modern society — that assemblage of men in which prostitution and its attendant evils are most rife.

Here the crowded state of the population, the constant and promiscuous association of the sexes in all grades of society, the sedentary occupations in which half of our youth of both sexes are engaged, indulgence in the pleasures of the table, the intemperate use of animal food and intoxicating liquors, the various amusements and temptations which, in all great centres of population, tend to excite the passions, and, above all, the struggle for existence that is always going on, along with the various obstacles in the way of early marriages—surely these are conditions which, as long as human nature remains as it is, will ever preclude self-control between the sexes exercising any sensible influence in mitigating the evils we are now considering. That, however, it might be practised more frequently than it is we will admit, and may hereafter show, but, in the meantime, we cannot help expressing our surprise that the Congress did not touch upon any of those conditions of education and hygiene under which such self-control might become more practicable.

The Section of Hygiene condemns, in view of their complete failure, all systems of *Police des Mœurs*, whose object is to regulate prostitution. As, in these systems, our own Contagious Diseases Act is necessarily included, this resolution deserves our especial attention. In the first place, it seems rather paradoxical that a section devoted to hygiene should condemn all systems of police whose object is to prevent those diseases which play so much havoc among communities, for to say that the object of these systems is merely to "regulate" prostitution is both a misrepresentation and an evasion of the main point at issue. The real and laudable object of not only our own Contagious Diseases Act, but even of the Continental systems, is the prevention of disease. To authoritatively sanction prostitution would be certainly highly immoral, but to prevent the spread of disease is religion. And on what grounds does this Section base its condemnation of any and all of these systems? Because "the obligatory surgical examination of women is revolting to human nature, because it can only be carried out in the case of a certain proportion of prostitutes," and because the diseases in question cannot always be discovered. The first of these arguments is one of the chief arguments that have been urged by the opponents of our own Act, but the fallacy of which it is by no means difficult to expose. The fact that any law or measure authorised by Government is revolting to human nature, is no reason why that law should be repealed. It is revolting to human nature that any man should be hanged; but would any one say that, for that reason alone, the hanging of desperate and hardened criminals should be entirely abandoned? Besides, if we regard the character of the criminal and the motive for his punishment, we should rather say that the apparently revolting nature of a penal Act should be attached rather to the crime and the criminal than to his punishment. It is far more revolting to human nature that a man should commit murder than that he should be hanged for it. The murder is a sad illustration of human depravity, but the hanging shows that Society has a conscience which condemns the crime by which it is disgraced. For the same reason the compulsory examination of prostitutes cannot be regarded as so revolting to our feelings if we keep in view the character or position of the prostitute and the motive the Government has for putting her under surveillance. For the same reason it is far more revolting to human nature that women should be found pursuing so vile a calling as that of prostitution, than that Government should endeavour to prevent the evil being aggravated by the disease which this class of women sows broadcast among the community. No Government would think of sanctioning prostitution as a necessity of Society, for that would be legalising immorality. The object aimed at by all systems of *Police des Mœurs* is the prevention of a certain class of diseases; and as the only way, as far as the State is concerned, of attaining this object is by putting the evil under some sort of control, it is most unreasonable to contend that the State thereby encourages profligacy and immorality.

Equally fallacious are the arguments that these compulsory examinations can only be carried out in a certain proportion of prostitutes, and that they have, in some instances, failed to answer the expectations at first formed of them. For, certainly, all the systems thus summarily condemned by the verdict of the Geneva Congress have not been a complete failure. With regard to our own Contagious Diseases Act and the system pursued in Belgium, recent official reports and the most reliable statistics prove that the operation of these Acts has been attended, not only with a great diminution of venereal diseases, but of prostitution itself. The argument of the Congress is therefore narrowed to the fact that all systems of *Police des Mœurs* have failed to fully accomplish the object which legislators had in view in framing them—a fact that is no more an argument in favour of abolishing them, than the prevalence of crime is an argument for the abolition of all penal codes. Should imprisonment, penal servitude, or even capital punishment, be abandoned because all sorts of crime are still rampant amongst us, because the law "can only be carried out in a certain proportion" of criminals, and because it is impossible to rely upon the detection of crime in every case? And on the same grounds we ask should the impossibility of the law reaching every case of prostitution, and the impossibility of detecting in every case the presence of disease, be any valid reason for repealing Acts which have been proved to fulfil, in a great measure, the objects for which they were passed—Acts, the operation of which has been shown to have even a beneficial effect in the interest of morality itself.

The Section of Hygiene also desires to see removed all obstacles against venereal maladies being as extensively treated in our general hospitals as other diseases are, but the Congress overlooks the fact that the greatest obstacle to the admission of prostitutes into the public hospitals, lies in their own prejudices and aversion to enter any voluntary hospital. Many of them even prefer to make money notwithstanding the fact that their external parts are covered with discharging condylomata capable of inoculating the disease. For this very reason it is an error to suppose, as one of our correspondents lately did, that voluntary or municipal lock hospitals do all that can be done in a free country like this to keep down the

spread of syphilis. The successful working of the Contagious Diseases Acts in those places where they have had a fair trial shows that something more than voluntary hospitals was wanting to check the prevalence of venereal diseases among our soldiers and sailors; and it has yet to be shown that all other systems, which seek through the regulation of prostitution, to prevent the spread of disease, have been a complete failure, or have been attended with evils worse than the mischief which it was their object to remove.

THE OXFORD SCHOOL OF MEDICINE.

We do not intend to be the champion of Dr. Acland, nor to discuss the vexed question whether the Oxford School of Medicine has been "extinguished" either by himself or Professor Rolleston. Our object, at present, is simply to direct the attention of the profession to the manner in which the controversy, which is now being carried on in the *British Medical Journal*, arose. The honour, not only of the profession, but even of medical journalism is at stake, and as guardians of medical ethics, we feel it our duty to enter a firm protest against a misapplication of power. The Association Journal occupies a different position from that of other medical papers. Its ethics should be of the highest character; it should give a tone to medical literature, and should be, uninfluenced by any of those various conditions, incident to proprietary journals. The advancement of science, the welding together of the profession into a more compact and united mass, the diffusion of sound medical opinions, the free interchange of thought, were some of the aims with which it was originated, and we may, in justice, say this programme has fairly been carried out. But we hold that a grievous error has been committed in connection with the attack recently made both on Professor Acland, and Professor Rolleston in its columns.

Anonymous publications are sometimes necessary and justifiable. They are beneficial under certain conditions, but all will agree with us that they are to be condemned when they are made the vehicle of personal animosity or abuse, and this offence is aggravated when it is masked under the guise of reform and science. These are general principles believed in by the majority of editors. As Englishmen we do not like the stiletto, for no man is safe from the attack of the assassin; and, similarly, neither virtue, honour, integrity, talent, or rank are protected from the assaults of the anonymous writer. Editors have, therefore, a sacred trust to discharge in protecting the public against such assailants. Holding these views, we were surprised at reading a letter in the *British Medical Journal*, of January 3rd, entitled a "Lost Medical School" and signed "A Member of Convocation."

It was not only remarkable for the statements it contained, but for the evident personal equation of the writer, for it was certainly distinguished neither by good taste, feeling, or a spirit of fair play. But the publication of the letter is not only suggestive; still more significant of a one-sided and therefore of an unfair action, are the two leading articles which have subsequently appeared, and which have taken the letter of "A Member of Convocation" as virtually proved and true.

On the faith of an anonymous correspondent Professors Acland and Rolleston are arraigned before the bar of medical opinion; they are accused of extinguishing a medical school; they are held "to be distinctly and personally responsible for something like treason to the faculty they represent and the profession in virtue of whose titles they hold their positions." In plainer English, they are charged with a coalition, thus forcibly put by Dr. Whittle:—"Here is a medical school; come, let us destroy it, and the emoluments shall be ours."

They are tried, for the *British Medical Journal* tells us that, having investigated the subject, the facts substantially are proved, and the decadence of the school at Oxford, if not caused by the learned professors is still *un fait accompli*. They are virtually found guilty as *participes criminis* without being heard, and the profession is invited to assist in the movement which will restore the departed glory of the Oxford school of medicine, and the restoration of the rights and privileges usurped by such men as Drs. Acland and Rolleston.

An anonymous communication is made the peg for an exciting and personal controversy, an anonymous communication is followed up by fervent editorials with titles, and thus the British Medical Association speaks, through its mouth-piece, in condemnation of the President of the Medical Council, and of one of its own past presidents. Such an abuse of power, if it occurred in any other contemporary, would be lamentable, it is still more grievous in a representative paper. Dr. Acland's life has been devoted to the elevation of the profession, his name is honoured as one of the pioneers of medical progress, whether for the advancement of medical education or medical interests, in their narrower and less scientific aspects, whilst the costly Museum of Physical Science at Oxford is a standing tribute both to his energy, untiring activity, and zeal in the cause of science. We have, therefore, *prima facie* evidence that Dr. Acland is not a man ambitious of sinecure, and that the interests and honour of the profession are as dear to him as they are to the writers in the *British Medical Journal*. He has not replied to his anonymous correspondent, and his reticence reflects credit upon him.

The *British Medical Journal* hoped to have had the benefit of Dr. Acland's remarks, but though the hook has been skilfully baited, yet the fish has not risen, and we feel sure that Dr. Acland will have too much respect for his own position and for his own honour, to break the dignified silence, which he has maintained. His life devoted to his profession, is an answer against any charge of forgetfulness of the interests of medicine or of treason against the faculty which he represents. His friend, Dr. Chambers, has come forward in his defence, and his letter in the journal of the 26th, already sufficiently indicates that the "Member of Convocation," as Dr. Chambers says, "must have known very little of the history of Oxford to apply the term 'Lost School.'"

Should a more legitimate opportunity occur for the discussion of the question of the position of Oxford as a school of medicine, we feel sure Dr. Acland will contribute to the elucidation of any points requiring explanation, and should his critics be bold enough to challenge him manfully and openly, we do not doubt but that the Regius professor

will be able to vindicate his honour and throw a different light on his actions.

One word as to Professor Rolleston. His name is above suspicion, and we may quote a sentence from the address delivered at the meeting of the British Medical Association at Oxford, 1868—applicable at the present time. He then said: "Dignity rests upon responsibility. A man is worthy or unworthy, accordingly as he can or cannot make a good answer when called upon by a voice either within or without, to account for his conduct or for his character."

When such an occasion arises, the eminent anatomist, physiologist, and biologist, will not shirk his duty.

But the time has not come; nor has the voice been raised to require a personal explanation of his motives, or to demand an explanation of the system of teaching which he deems most conducive to the well being of his own special branch of medicine.

Notes on Current Topics.

Professional Advertising in Dublin.

Our attention having been called a second time, to an article appearing in the *Dublin Mail* of the 30th ult., in reference to the Orthopædic Hospital, situated at Usher's Island, we find ourselves called upon to observe upon the nature of that article and the grave impropriety involved in the publication of such communication in the public daily press. The principal portion of the article in question, consists in a detailed description of the cases in the institution, the nature of the deformity depicted in moving terms, the difficulty, perseverance, and skill of the treatment, and, finally, the beautiful perfection of the result achieved. A case treated by Sayre's apparatus is given. The treatment described as "marvellous." The boy, we are told, entered the ward like one "of the quadrumana, but, with the plaster armour on him, he rose from his bed, and walked briskly and erect across the ward. The *vis medicatrix naturæ* will do the rest, throwing up a bony formation which will knit together the injured portions of the column." We are not concerned with the Dublin Orthopædic Hospital in this matter, further than to remark that it is by no means the only institution in Dublin where these miracles of healing are performed, and the inference that patients must die in their deformity or resort to Usher's Island, is in no way justified. It is, however, our duty to call attention to what we consider a gross breach of professional decorum, all the more open to censure, because it is perpetrated under the apparent cognizance of a surgeon or surgeons who have sworn to sustain the "reputation, honour, and dignity" of their profession, who have on a former occasion, been reminded of the impropriety of this form of advertisement, one of whose names is prominently set forth in this newspaper puff, and whose name plate is effectually displayed on the door of the Institution in which these wondrous cures take place.

We condemn most emphatically the system of recording the surgical achievements of any practitioner in the daily papers, being apprehensive that, if the transaction pass unnoticed, we shall yet see the miseries of blindness, the minutiæ of a cataract operation, and the heaven of perfect vision (under the auspices of Dr. ——), paraded in our breakfast table literature day by day, or the agonies of an inward tumour, the perils of ovariotomy and the miracle of restored health (under the care of Mr. ——), set forth with all detail in our monthly magazine.

The surgeon who permits such publications to emanate from an institution with which he is officially connected, and in which he has influence, cannot be excused on any plea that the communication did not emanate from his own pen. To walk from bed to bed with a reporter supplying to him the pabulum, is just as unmistakable an infraction of propriety as to pen the article in the privacy of one's study, and, if the surgeon in charge be guiltless of thus priming the press, it is, at least, consistent with his self-respect that he should repudiate a proceeding with which his name is so directly connected.

We greatly regret to be obliged to observe that the profession in Dublin, as in one or two other cities, has, of recent years, not advanced in estimation of the self-respect which is due to itself as a profession of gentlemen and men of science.

The creed that success by any means, professional or unprofessional, justifies the means seems lately to have many admirers, and, even colleges, which have hitherto occupied the position of guardians of professional honour, have been slow to speak, even when the proceedings of their own fellows are in question. We claim, at least, for the whole professional community, perfect freedom of action, and the right to employ the same means which others employ without rebuke. If the daily press is to be invoked for the advertisement of one institution or practitioner, and with the implied approval of the profession, then, in our opinion, it is most unjust that any other should be condemned for resorting to the newspapers for publicity.

Vaccination Penalties.

A Bill before the House of Commons, promoted by Mr. Pease, Mr. Walter James, Mr. Mundella, and Mr. Leeman, recently printed, proposes to amend the law relating to vaccination so far as accumulating penalties are concerned. The Bill runs thus:—"After the passing of this Act no parent of a child shall be liable to be convicted for neglecting to take, or to cause to be taken, such child to be vaccinated, if either he has been previously adjudged to pay the full penalty of 20s. for any of such offences with respect to such child, or he has been previously twice adjudged to pay any penalty for any of such offences in respect of such child." The Bill is appointed to be read a second time on April 3rd next.

Rejections at the London College of Surgeons.

We understand that during the late examinations at the Royal College of Surgeons of England, of the 110 candidates examined, 44 having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their anatomical and physiological studies for three months. This large number of failures, says the *Student's Journal*, will not excite much wonder, however, in face of the fact that, out of the 110 candi-

dates examined, no less than *fifty-one* offered themselves a second time, six for the third time of asking, three for a fourth time, and one for a fifth time; and of this number, sixteen were again rejected. The proportion of rejections is lamentably high, and at first sight is strongly suggestive of grave inefficiency of teaching power; but the fact that nearly 50 per cent. of the candidates had been rejected before, some of them several times, appears to point pretty clearly to a different cause for such numerous failures—to a cause inherent in the candidates themselves, and not to defects in the system of education. Does it not seem clear that a considerable number of these gentlemen have mistaken their vocation, and that, even should they (after three, four, or five failures) succeed in getting qualified, they never can hope to succeed in practice?

Intemperance among Women.

THE largest meeting which has taken place at the Mansion House for some time was held on Thursday last under the auspices of the British Women's Temperance Association, the object of the gathering being "to impress ladies with the importance of their influence in the cause of total abstinence from all intoxicating drinks." The Rev. Canon Duckworth, in the absence of the Lord Mayor, presided and addresses were delivered by Mrs. Lucas, Mrs. Scholefield, Mrs. Fowler, Mrs. Firth, and others.

The object of this Association is a laudable one, and we hope to hear that their efforts have been crowned with success. The task, however, ladies have set themselves is by no means an easy one. Unfortunately, there is a good deal of intemperance among women of all classes of society. Even young ladies who, a generation ago, would never have taken anything stronger than water or a little mild ale, now think nothing of drinking two or three glasses of wine, and sometimes a little spirits as well. We should also like to know what this Association thinks of the grocer's licence, which is supposed to be particularly favourable to intemperance among women. If the growing propensity among women to indulge in alcoholic beverages is to be permanently checked, it is our daughters upon whom we should chiefly impress the importance and advantages of total abstinence. This should be done not only by precept but by example; for much of the drunkenness prevalent among the women of the lower classes is, unfortunately, due to the bad example that has been set them by their parents.

The Propagation of Disease.

IT transpired at an inquest held a few days ago, that the elder child of William Drake, a painter and paper hanger, residing at Chappel Row, Exmouth Street, Clerkenwell, was attacked with what her father thought was chicken-pox, and recovered; but that ten days later another child, five years old, also became ill and died. Then it was discovered for the first time that it was a virulent case of small-pox. Drake and another child slept in the same bed as the deceased, and during her illness one of the children continued to attend Trinity Schools, Gray's Inn Road, where there were upwards of 300 children. Several of the jurymen asked for the removal of the members of the family, who were present, from the court, and in their verdict they attributed the death to the want of medical attendance, owing to the ignorance of the parent.

This case forcibly illustrates one of the difficulties which will lie in the way of carrying out the proposed system of registering all cases of infectious disease. It shows that such a system might be more successfully carried out by making the parents responsible for the information to be given to the registrar, than by fixing the responsibility upon the medical attendant.

Our Reports on Rabies.

WE were gratified to notice that attention was drawn to this absorbing topic in the House of Commons on Thursday night, the Government promising to take action upon it at an early date. The interest appears to be general throughout the country, if we may judge by the number of letters, cases, and cures, real and imaginary, which we have received throughout the progress of our Reports, commenting upon which, the organ of the veterinary profession, the *Veterinary Journal*, for February, says:—"The literature of this malady is indeed advancing at a wonderful rate, and it is almost daily receiving additions. Perhaps the most valuable and complete treatise is to be found in a series of articles which are now appearing in the MEDICAL PRESS AND CIRCULAR, and which we can highly recommend to those who are studying the subject, either in man or animals."

The Manchester Children's Hospital.

THE Staff of the Manchester Children's Hospital has lost by the resignation of Dr. Borchardt a most valuable member. Connected with the Institution when it was first started as a small dispensary, Dr. Borchardt has been the chief motive power towards building up that which has attained to the position of a large well-managed pavilion hospital. Through his exertions, also, the staff receive honoraria for their services, varying from £400 to £100 per annum each; an example which we should be glad to see more generally adopted. Dr. Borchardt carries with him in his retirement the universal respect of all with whom he has been associated.

Hospital Sunday Fund and Surgical Appliance Societies.

THE somewhat important question of admitting Surgical Aid and kindred societies to participate in the distribution of the Hospital Sunday Fund, came on for discussion at a meeting specially convened to consider the question, last week, at the Mansion House. A fortnight or more since, and as we then stated, a resolution was submitted to the Council, having for its object the bringing these societies within the operation of rule 4, thus enabling them in future to participate in the distribution of the Hospital Sunday Fund. By a particular line of special pleading, it was sought to bring Surgical Appliance Societies within the rule, because it was said these societies supply a truss or wooden leg, as part and parcel of the hospital treatment, and consequently partook of the nature of dispensary work, inasmuch as the cure was not complete without the surgical appliance. At the

special meeting an attempt was made to settle the question on this basis, and it was accordingly moved that "an instruction be issued to the Committee of Distribution to include Surgical Aid and Appliance Societies, as well as truss societies, in the category of dispensaries." After a considerable waste of time in the discussion of this abstract form of resolution, it was eventually withdrawn and a wiser policy allowed to prevail. It could not be denied that the action of some of these societies was at least not so very commendable—that it was high time some change should be made in the mode of dealing out their charity to poor applicants. We have had on several occasions to point this out, and show that a gross amount of injustice is inflicted by requiring maimed patients to stump London, begging for letters "to cover the expense" of a wooden leg, or crutch as the case may be. It cannot be denied that a great injury is inflicted on these poor people by the existing system; assistance to be effectual should be immediate, and given without unnecessary trouble and delay. The Council of the Hospital Sunday Fund, fully recognising this principle, unanimously adopted the following resolution:—"That it be referred to the Distribution Committee to confer with the societies or managers of the Surgical Aid and other societies, with a view of ascertaining whether these societies were prepared to modify their rules and practice, in order to secure to the poor the means of obtaining surgical appliances by one letter, instead of throwing on the suffering patients the labour of soliciting a number of letters in almost each case; and whether those objects could be obtained by means of the Samaritan agencies attached to the several hospitals, and to report to the Council."

Bequests to Medical Charities.

THE Seaside Convalescent Hospital, Seaford, has received £1,025 8s., less duty, under the will of Mr. William Thomas, of the Boltons. The executors of the will of MRS. Gibson have apportioned £500 each to the Warneford, Leamington, and South Warwickshire Hospital, the Coventry and Warwickshire Hospital, and the Birmingham and Midland Free Hospital for Sick Children. Mrs. Margaret Collins Lambert, of Finchley, bequeathed £500 to the Monmouth Hospital. Mr. Robert Alexander Grey, of Camberwell, bequeathed £100 each to the Seamen's Hospital and the Earlswood Asylum for Idiots. "H. S. C." has given £100 to the Charing Cross Hospital. Mr. Hozier, of Maudslie, bequeathed £200 to the Western Infirmary, and £100 to the Ophthalmic Institution; all at Glasgow. The Misses Brooke have given £1,000 to the Adelaide Hospital, Dublin, £300 to the City of Dublin Hospital, £200 to the Rotundo Lying-in Hospital, and £100 to the Cripples' Home, Bray. Mr. Smyth has bequeathed £200 to the Adelaide Hospital, Bray.

Rules for Living.

"WHEN doctors disagree," &c., is an axiom of considerable antiquity; to illustrate which still further, an American contemporary, has fished out of about a dozen journals, devoted presumably to public health and sanitary matters in this country and America, the following rules, which, if any of our readers will kindly try and give us their experience, will doubtless add much to our knowledge of therapeutics generally. 1. Rise with the sun. 2. Never rise before 7 o'clock. 3. Drink a glass of cold water before breakfast, 4. Never drink until you are through eating. 5. Eat nothing but Graham bread and vegetables. 6. Eat plenty of roast beef and mutton well done. 7. Bathe every day. 8. Never bathe oftener than twice a week. 9. Always sleep in a cold room. 10. Never sleep in a room with the temperature lower than 45 degrees. 11. Drink nothing but water. 12. Drink nothing but milk.

Curara in Epilepsy.

DR. F. KUNTZE, in a recent number of *Deutsche Zeitschr. f. prakt. Med.*, suggests the employment of subcutaneous injections of 0·5 grm. (gr. 7½) curara in 5 grm. (℈iv.) water with the addition of two drops of hydrochloric acid. Eight drops of this solution are injected, in adults, at intervals of a week. In a number of cases in which this method of treatment was employed, a few weeks sufficed to bring about a marked amelioration in the epileptic symptoms.

Copious Bleeding in Puerperal Eclampsia.

APROPOS of the subject of the revival of blood-letting, on which last year we dwelt at some length, we read in the *Journal des Sages Femmes*, November, 1877, that Prof. Depaul insists that copious bleeding from the arm is the only method of treating eclampsia which meets with success. He refers to an experience of 250 such cases. The introduction of premature labour he considers tedious and provocative of fresh convulsions. He also advises bleeding as prophylactic treatment.

AT Guy's Hospital both surgeries and the operating theatre are now connected direct with the electrifying room, so that the surgeon may have the current at his disposal at any time when he may require it. He presses a small stud, which rings a bell in the electrician's room, and points out on an indicator where the current is required. The latter is then turned on without loss of time. At night the operator can obtain the current by the simple movement of a spring, the indicating apparatus in the battery-room registering the fact, and also betraying the negligence of the operator if the current is not turned "off" when not required. The arrangements are complete, and work satisfactorily, and Mr. Seymour contemplates carrying them out in the medical wards, so as to avoid the necessity for shifting heavy batteries to that part of the hospital where the current is required.

THE "Comité de Propogation pour l'usage Alimentaire de la Viande de Cheval" have addressed a petition to the Lord Mayor asking him to give authority to open two shops in London for the sale of horseflesh as food The Lord Mayor has, of course, replied that in this free country no authority is needed to carry on a business, and his permission, therefore, is not necessary for the experiment to be tried.

Dr. Wilson Fox, having requested an opinion of the Council of the British Medical Association relative to the unrestricted admission of women to the meetings of the said Association, has been informed that women cannot be excluded. In consequence of this decision, Dr. Fox has requested his name to be withdrawn from the list of members of the Association, and we hear that it is not improbable that others may follow his example. The matter is one of individual opinion; but Dr. Fox thinks it right to call the attention of the profession to the question as to "how far public discussions on medical topics, at which men and women are present, and on which no restrictions are placed, are consistent with the rules of propriety and delicacy, which have hitherto been generally held to obtain in the relations between the sexes."

A very sensitive reagent for alcohol, and one that is very simple in its mode of application, has been found by M. Jacquemart. It is a solution of nitrate of mercury obtained by treating the metal with a little nitric acid of average concentration. The action is vigorous and rapid. The mercury is brought in part to the minimum of oxidation, and if a little ammonia be added to the mixture, after the reaction, a dark precipitate is obtained, which is darker the more there is of alcohol in the product suspected. Methylic alcohols and similar liquids do not give a dark precipitate with ammonia.

The Dublin Obstetrical Society will meet on Saturday the 9th, at 8 o'clock, at the College of Physicians, when the following communications are set down for reading:

Adjourned discussion on "Transfusion." Dr. Denham on "An Improved Ecraseur." Dr. Purefoy on "The Hypodermic Injection of Chloral in Puerperal Eclampsia." Dr. Macan on "Milk Fever." Surgeon-Major Johnston on "Puerperal Remittent." Dr. Atthill, "The Clinical Report of the Rotunda Hospital for the Year ending 5th November, 1877.

Last week's mortality bears very favourable comparison with the preceding weeks in January in nearly all the large towns of the United Kingdom. Edinburgh and Birmingham returned 24 deaths per 1,000 of the population, Manchester 26, London, Glasgow, Liverpool 27, and Dublin 29. Whooping-cough was excessively fatal in Brighton and Plymouth, whilst the deaths from small-pox in London declined to 34. There was no death reported from this latter disease in any provincial town in England.

St. Petersburgh still occupies the unenviable position of being the most unhealthy city in Europe, having a death-rate of 46 per 1,000 of the population. That very filthy city Buda-Pesth comes next on the list with 44, with Venice 42, Turin 38, Rome 33, Vienna and Naples 32, following in the wake.

A man has just died at Hounslow, named John Rhodes, leaving over £100,000 to the various metropolitan charities During life he dressed like a tramp, and denied himself the common necessaries of existence.

We regret to announce that the Medical Microscopical Society of London, which has done valuable work during the past few years, has now ceased to exist for want of adequate support.

The *Chicago Medical Examiner* gives the following statistics on anæsthetics:—

		Administrations.
Chloroform .	One death in	2,723
Ether and chloroform (mixed)	,,	5,558
Bichloride of methyline	,,	7,000
Ether . .	,,	23,204
Nitrous oxide . .	No deaths in	75,000

The consumption of beer in Germany was in 1872, 53·4 litres per head; in 1873, 66·80 litres; in 1874, 70 litres; and in 1875, 72 litres.

It appears from the "Medical Directory" for the present year, that out of 336 coroners in England and Wales only 48 belong to the medical profession.

DR. LUSH'S BILL.

The following is a copy of the Bill referred to in our last:—

"Whereas an Act was passed in the twenty-first and twenty-second years of the reign of Her Majesty to regulate the qualifications of practitioners in medicine and surgery; and whereas it is expedient to amend the Act:

"Be it therefore enacted, &c.:

"1. Section forty of the said recited Act is hereby repealed; and in lieu thereof it is enacted: Any person who for the purpose of gain shall take or use the name or title of physician, doctor of medicine, licentiate in medicine, licentiate in surgery, bachelor of medicine, surgeon, general practitioner, apothecary, or any other medical or surgical name, title, or description purporting to authorise the practice of medicine or surgery, unless such person holds a qualification or qualifications entitling him to take or use such name, title or description, and such qualification or qualifications be also registered under the said recited Act, shall, upon summary conviction for either or any such offence pay a sum of twenty pounds.

"Any person who for the purpose of procuring the registration of the cause of death of any deceased person shall make, fill up, or sign any medical certificate of the cause of such death, unless he personally attended such deceased person during his or her last illness, and holds a qualification in medicine or surgery duly registered under the said recited Act, shall upon summary conviction for either or any such offence pay a sum of twenty pounds.

"If any person shows that he is not a British subject and not ordinarily resident in the United Kingdom, and holds a medical diploma, degree, or title from some university, college, or body in any British possession or foreign country entitled to grant the same, such person shall not be liable to any penalty under this section.

"3. To schedule A of the said recited Act this section shall be added: When the General Medical Council are satisfied that any medical diploma, degree, or title granted by any university, college, or body in any British possession or in any foreign country is granted in respect of a degree of knowledge in both medicine and surgery equal to that required for obtaining a licence in both medicine and surgery under the said recited Act, they may from time to time, if they think fit so to do, place such diploma, degree, or title upon the medical register, and if at any time any such medical diploma, degree, or title ceases to be granted in respect of such degree of knowledge as aforesaid they may remove the same from such register.

"5. This Act may be recited for all purposes as the Medical Acts Amendment Act, 1878."

Correspondence.

TRACHEOTOMY IN DIPHTHERIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Two points of special practical importance occurred to my mind in reading Mr. Thornton's letter in your issue of January 30th ; (1) the absolute suddenness of death in cases of diphtheria, and the impossibility of restoring life by artificial respiration after the trachea has been opened ; and (2) the necessity for the use of a large canula in tracheotomy. I have not been so fortunate as to see Surgeon-Major Quill's paper.

1. *Mode of Death in Diphtheria.*—Some years since, my colleague, Mr. Partridge, requested me to watch a young native adult just admitted to the Calcutta Med. College Hospital with diphtheria. He was in a very low state, the soft palate and pillars of the fauces were disintegrated by sphacelus, and suffocation was threatened. Having other cases to visit, I desired that the instruments might be ready in a side room, and passed and re-passed the bed frequently. Coming before him, I saw a sudden change in his countenance, froth gathered about the lips, and he died instantaneously. I called for the instruments, which were brought after I had, without a second's delay, bared the trachea with my penknife. Artificial respiration was immediately employed, but not the faintest sign of vitality could be evoked. I, as speedily, opened the trachea in a fine European boy of four, whom my colleague, Sir Joseph Fayrer, requested me to watch. Here, too, the body was as irresponsive to immediate and perfectly free artificial respiration as if it had been two days dead. Precisely the same occurred in a young child which died of whooping-cough; but, in that case, the air-tubes were full of fluid, which they were not in the other two cases. These cases are strongly contrasted with that of a man who was suffocating from syphilitic laryngeal mischief. It was the etiquette of our hospital that I should send for a surgeon. I did so, and waited until the man fell over. I then opened the trachea, and free respiration was at once restored. Again, these cases of diphtheria are contrasted with the following one. I was in the operating theatre when a nurse ran in and called me into a neighbouring ward. I there found a sickly-looking native, who, having for some weeks worn a tracheotomy tube, had, upon a sudden caprice, taken it out and—died. I re-introduced the tube, and commenced artificial respiration, with little hope of benefit, as all breathing must have been suspended for at least four minutes. Respiration was speedily restored, and the man was able to run away from the hospital on the following day. The clear inference is that, in diphtheria, death is immediate and absolute, and due to some central lesion, and that, consequently, if we are to open the trachea in this disease, it is useless to do so at the cessation of respiration.

2. In the case of true hydrophobia in which I opened the trachea, the laryngismus which had been present ceased immediately upon the introduction of a very large canula, and the patient drank freely *once*. In my narrative of that case I insisted strongly upon the extreme necessity of employing as large a canula as possible in all cases of tracheotomy. I was led to adopt this precaution, throughout my practice, after attending the autopsy upon a man with syphilitic disease of the larynx, who died suffocated with, and in a great measure by, an impracticably small tube which had been introduced into his trachea.

Yours faithfully,
NORMAN CHEVERS, M.D.

London Hospital Medical College,
1st February, 1878.

THE ADELAIDE HOSPITAL, DUBLIN.

WE understand that the circumstances following upon the resignation of the surgeoncy of this Hospital by Dr. Albert Walshe, to which we referred last week, have received a further development in the resignation by Dr. Montgomery A. Ward, of the assistant-surgeoncy of the Hospital, held by him for ten years, he having had reason to believe that the appointment of a young gentleman, now resident in North Wales, had been decided upon by the ruling party in the medical board. Allowing to this gentleman every qualification which he can be conceived to enjoy, we cannct but express our regret that an officer who has, as we believe, done his duty with every credit to himself and the Institution for so many years, should be slighted and deprived of the fair reward of his labour, in order that his place might be given to an entirely untried candidate. The Adelaide has been foremost in adopting the excellent system of probationary assistant-surgeoncies, and it does not do itself justice when it ignores the implied contract with a deserving officer like Dr. Ward. Recent hospital appointments in Dublin have given special interest to the subject, and it certainly seems to be high time that public attention should be directed to the system under which men of experience and professional rank are habitually replaced by young men entirely unacquainted with the hospital management, and unaccustomed to practical surgery.

THE BRITISH MEDICAL ASSOCIATION (DUBLIN BRANCH)

THE First Annual Meeting of this Branch, which has within the last twelve months been organised with great energy by the hon. sec., Dr. Duffey, was held on Wednesday last, at the King and Queen's College of Physicians. The chair was occupied by Dr. Hudson, Physician to the Queen, and the parent Association was represented by the President, Dr. Wilkinson, and by Mr. Ernest Hart. The local branches in Ireland also sent representatives ; Dr. Curtis and Dr. H. Macnaughton Jones from Cork, and Dr. Cuming and Dr. Moore from Belfast. The attendance was numerous, and the Report of Council for the past year satisfactory and encouraging. In the evening the members dined together in the College Hall, the chair being occupied by Mr. Porter, Surgeon to the Queen in Ireland, and the entertainment proved in all respects a success.

Obituary.

DR. CHURCHILL, OF DUBLIN.

WE regret to have to announce the death, on the 31st ult., at Ardtrea Rectory, of Dr. Churchill, long known as an eminent obstetrician, until failing health and the strain imposed by the arduous duties of his extensive practice compelled his retirement in 1875. In the case of one whose attention to business was so unremitting as Dr. Churchill's, the record of the several steps by which he ultimately placed himself among the leading members of his profession is, in a certain sense, the record of his life. In conjunction with Dr. Speedy he founded the Western Lying-in Hospital, which did much for the poor in that quarter of Dublin, and he was, in 1856, appointed Professor of Midwifery to the School of Physic in Ireland, holding the office until 1864. In both the former and the latter year he was President of the Obstetrical Society, and during the years 1867 and 1868 he was President of the King and Queen's College of Physicians. On his retirement from the profession, in 1875, he presented his valuable obstetrical library to the College of Physicians, the College, in their turn, presenting him with an address couched in flattering terms, and directing his portrait to be painted and placed along with those of many other illustrious members of their body in the College Hall.

Dr. Churchill took his first medical degree in Edinburgh in 1831, and in 1851 had the honorary medical degree of Dublin University conferred on him. He was a voluminous contributor to medical literature, and the author of various works on his special branch of practice; and these, as well as his works on the diseases of women and children, were for a quarter of a century the standard text-books on the subject, and have, indeed, been republished in America,

and translated into European languages. He was also the translator of a valuable series of papers on "Puerperal Fever" for the Sydenham Society in 1849. At the meeting of the British Medical Association at Norwich, in 1874, he was chosen President of the Obstetrical Section, but from failing health he was unable even to attend the meeting. The address which he had prepared on "The Hygiene of the Lying-in Hospitals" was, however, delivered.

He died on Thursday morning, Jan. 31, at the rectory of his son-in-law, Ardtrea, near Stewartstown. He adds another to that bright roll of venerated names on which the medical men of Ireland have found an honoured place and memory.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Mr. Rundle will please receive our thanks.

Telephonic Auscultation.—A correspondent in the *Student's Journal* of Saturday has the following :—"In my last letter I suggested that the telephone might be used for the purpose of diagnosing heart and lung diseases. I scarcely expected to be called upon just yet to announce that the idea has been carried out, but I observe that a correspondent of the Medical Press and Circular states that he has been able, with the telephone, to hear the sounds of the chest, distinctly, at a distance of thirty yards. The time may come when our fashionable physicians will have consulting-rooms in the large provincial towns, each having telephonic communication with his London consulting-room, where he will sit, examine, and prescribe for those patients who would find it inconvenient to come up to town to consult him. Of course, patients would have to attend at the provincial consulting-room at such times as he would appoint. Bristol patients could attend at 10 o'clock a.m., Birmingham at 10.30, Oxford at 11, and so on. There would probably be some difficulty about the fees; they could not be transmitted by telephone. But these could be paid to an agent or secretary," who might bolt after receiving sufficient to make it worth while.

Histologist.—Dr. Thin, who read the paper "On the Proportion of Red Corpuscles in the Blood," is author of the work on "Practical Histology," to which you refer.

A. R. M. should write at once to the Director of the Army Medical Department.

Royal Institution.—Thursday, Feb. 7, at 3 p.m., Professor Dewar, "On the Chemistry of the Organic World."

Harveian Society.—Thursday, Feb. 7, at 8 p.m., Mr. H. Casson, "On Gunshot Injury of Elbow-joint."—Dr. Fitzpatrick, "On the Defective Drainage of West-end Houses, and Cases of Zymotic Disease arising therefrom."

Medicus.—The effect of the decision in the case of Jacob *v.* Finley (Dublin Coroner' Medical Witnesses) is, that in the opinion of the Court the employment of one individual as medical witness in all cases of inquest is illegal, and his payment by salary also illegal. We understand that Dr. Jacob, on behalf of the Irish Medical Association, has served notice on the Public Auditor that he will again object to such payments if allowed by him in his audit of the Corporation accounts.

Clinical Society of London.—Friday, Feb. 8, at 8½ p.m., the President: Specimens of Tendon Ligatures.—Mr. Nunn, "On Two Cases of Cancer."—Mr. Hutchinson, "On Retinitis Hæmorrhagica; its Connection with Gout, and probable dependence upon Thrombosis of the Veins."—Dr. Balmanno Squire, "On Severe Psoriasis treated by Daily Immersions," and a "Case of Psoriasis treated by Chrysophanic Acid" (living specimens).

Dr. Offenberg, Wickrath, Rhenish Prussia.—We have received a reply from Dr. Fort, of Paris. The article in *Le Progrès Medical* was taken from No. 49 of the "Journal of Surgery," &c., published by Dr. Fano, of Paris. The case with Dr. Polli's name was also published in the Annals of the Medico-Chir. Society of Liège, March and April, 1876. Dr. Davreux translated it from the *Annali dal Dr. [G. Polli.* Other references are the *Gazette Med. Ital. Prov. Venete*, Feb. 26, 1876, and the *Allg. Med. Berlin. Centr. Zeitung*, No. 2, Jan. 3, 1876. We would advise you to send us the German reference. We would also recommend you to write to Dr. Polli. It is highly important in the interests of science and justice that this question should be settled. At present it is involved in considerable doubt. The age of the patient is given in all the French papers as *twelve years*, the name of the medical attendant as Dr. Polli. Your name is not mentioned, and, unless it is a separate case, we cannot account for the facts being so different to those you represent. We shall be glad to hear from you as soon as you have made inquiries. Our "Report," as you know, is coming out in book form, and as this will be widely circulated the disputed points should be settled at once.

J. G.—There is no special skin hospital in Dublin. We cannot select a medical adviser for you, but no doubt your present medical attendant can tell you who he thinks most competent in dermatology.

VACANCIES.

Brecon Infirmary.—House Surgeon. Salary, £100. Testimonials, &c., to the Secretary on or before the 11th inst.

Clifden Union.—Medical and Sanitary Officer for the Clifden Dispensary District. Salary, £90, exclusive of fees. Election, 13th inst. (See Advt.)

Kent County Lunatic Asylum.—Assistant Medical Officer and Dispenser. Salary, £165, with extras. Applications to Allen Fielding, Esq., Canterbury.

Lincoln Lunatic Hospital.—Medical Superintendent. Salary, £150, with board, lodging, and washing. Applications to R. Hall, Esq., 38 Silver Street, Lincoln. (See Advt.)

Manchester Hospital for Sick Children at Pendlebury.—Medical Officer. Salary, £100, with board and residence. Applications to the Chairman of the Board. (See Advt.)

St. George's Hospital.—Surgeon and Assistant Surgeon on the Staff. Candidates must have the diploma of F.R.C.S.Eng. Applications, under cover, to the Hospital before the 13th inst.

Tobercurry Union, Coolaney Dispensary.—Medical Officer. Salary, £100. Election, 11th inst.

Westminster Hospital.—Aural Surgeon and an Assistant Surgeon, both Honorary. Election, Feb. 26. Candidates must attend a meeting of the Board on the 19th inst., with testimonials.

Wilts Pauper Lunatic Asylum.—Medical Superintendent. Salary, £600, with furnished apartments. Endorsed applications, "Medical Superintendent," before the 12th February, to be addressed to the Clerk of Committee, Devizes.

APPOINTMENTS.

Davies, J. H., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the North District of the Llandilofawr Union.

Evans, D. T., M.R.C.S.E., House Surgeon to the Salford and Pendleton Royal Hospital.

Hay, J. H., M.B., C.M., M.R.C.S.E., a House Surgeon to the Royal Maternity Hospital, Edinburgh.

Johnson, J. F., M.B., C.M., L.R.C.P.Ed., L.R.C.S.Ed., a House Surgeon to the Royal Maternity Hospital, Edinburgh.

Popeyt, Mr. A. J., a House Surgeon to the London Hospital.

Army Medical Department.—Surgeon-Major F. A. Elliott, M.D., promoted from half-pay to Surgeon-Major. Surgeon A. Irwin has resigned his commission.

Deaths.

Cameron.—On Jan. 21, at Whiteinch, Partick, Glasgow, Angus McCrae Cameron, L.F.P.S.G., aged 32.

Edlin.—On Jan. 21, at Levenshulme, Manchester, Ebenezer William Edlin, L.F.P.S.G., aged 47.

Paine.—On Jan. 27, at Crockherbtown, Cardiff, Francis Trevor, the beloved son of Henry James Paine, M.D., aged 25.

IRISH POOR-LAW INTELLIGENCE.

CARRICK-ON-SUIR GUARDIANS.

MEDICAL CERTIFICATES FOR HEALTHY PAUPERS.

In the case of Bridget Dwyer, who applied for out-door relief, but was too ill to attend personally, the Chairman asked if a doctor's certificate had been obtained to show such was the fact?

The Clerk said that the following vague certificate was had by the relieving officer from Dr. Ward :—"I certify that on yesterday I visited Bridget Dwyer, residing at Pill Road.—M. L. Ward."

Chairman—He does not say whether she is ill or well.

Relieving officer Power said that Dr. Ward refused to give such certificates any more.

Mr. Wallace—Did he refuse to give certificates?

Relieving-officer—I sent Dr. Ward a "red ticket" in order that he might visit this woman, and he said he would not act on it, as he was already attending her and giving the medicine required.

Mr. Wallace—What was the necessity for sending him another ticket if he was in previous attendance?

Mr. Walsh—It was to compel the doctor to visit the patient again, in order that he might give the relieving officer a certificate to produce here.

Mr. Wallace—Am I to understand that the doctor refused to attend on the "red ticket?"

Relieving officer—Yes. I sent the doctor a "red ticket," and he asked me why I did so? I said the way he would give me a certificate to show here when the out-door relief would come on. "I won't give it to you," said he.

Clerk—It strikes me that the whole question turns on the definition of the word "patient." How can Mr. Power issue a "red ticket" for a person in perfect health? (Laughter).

Chairman—I cannot give the relief sought for in these cases, if we have not the proper certificates as regards the persons who apply.

SLIGO UNION.

ADDITIONAL FEES FOR CONSULTATION WITH WORKHOUSE MEDICAL OFFICERS.

The Local Goverment Board wrote, in reference to a fee paid on the 1st inst., to a doctor who, on the requisition of the relieving officer, assisted the medical officer of the worknouse in a difficult surgery case, in the workhouse hospital. The Local Government Board wrote, saying that the relieving officer's powers under section 7 of the Act 10 Vic., cap. 21, did not apply to inmates of the workhouse. Assistance of this kind could only be, in strictness, granted by the guardians, but, if in a case of emergency, the medical officer should be obliged to seek additional medical aid, it would be competent for the guardians, should they see fit, to ratify the proceedings subsequently.

Chairman—It appears it is the guardians and not the relieving officer our doctor should apply to.

Mr. L'Estrange—Or the doctor can call in a doctor on his own responsibility, and come to us afterwards to ratify what he has done.

A letter was also read from Dr. Hamilton, in reference to the explanation he was called on to give, about his having, on a late occasion, called in Dr. Roe, of Cliffoney, who asked the guardians to pay him a fee of two guineas. Dr. Hamilton wrote to say that he was unwell the greater part of the night owing to over work, and, although better the next morning, he felt quite unequal to undertake the case, and he requested the relieving officer to procure the assistance of Dr. Roe.

RESIGNATION.

Mr. L'Estrange—Here is Dr Hamilton's resignation come in, after forty years' service.

Mr. Cogan—That is to be regretted, for he was very kind to the poor people.

Mr. L'Estrange—His was a long service.

Mr. Cogan—And he was a very clever man. During his forty-two years' service I believe there never was a complaint lodged against him.

SANITARY.

The Chairman then read the following letter from the Local Government Board, transmitting a copy of a report made by the medical officer of the Carney District to the Registrar-General, relative to the sanitary condition of the district :—

[Copy.]

"The deaths during the last quarter are far above the average—sixteen at an advanced age, and ten up to the age of five years. There is a total absence of drainage where the diphtheric cases occurred, and it is possible the disease may have resulted from that cause. The dwelling is one of a range of houses on the side of the main street, in the villiage of Carney, and the entire range is destitute of drainage and sewage, and in wet weather the floors of some of those houses are saturated with damp. I reported the matter to the sanitary authority; but the landlord, to whom it was referred, has done nothing to remedy the evil. In the district generally, however, our sanitary condition has improved, and we have been for a long time free from any serious epidemic."

It was agreed to refer the matter to the dispensary committee.

LIMERICK UNION.

ELECTION OF A RESIDENT MEDICAL OFFICER.

Before proceeding with the election the Chairman

thought they should dispose of the notice of motion given by Ald. Phillips, to the effect that it would be proposed to have the salary reduced from £200 to £150 a year. Lord Clarina had also given notice to have a committee appointed for the purpose of inquiring into the qualifications of the candidates seeking the vacant office.

Ald. Phillips then moved that the salary of the office be reduced to £150 a year. The workhouse hospital would be an excellent school for a young professional man, and he believed £150 a year with apartments and rations would be sufficient remuneration. He had no doubt that if at the end of a year they found that the new man had exhibited expertness and ability in the discharge of his duties the guardians would increase the salary to £200. But it was their duty, in justice to the ratepayers to reduce the expenditure wherever they could legitimately do so. He had made up his mind for a certain candidate who would, he believed, be willing to accept £150 a year.

Lord Clarina seconded the resolution. The reason, he said, that he had given notice to appoint a committee to inquire as to the qualifications of the candidates, was because he had expected there would be twelve or fourteen seeking the office, and in order that the best man should be selected. Now, however, that there were only three candidates, he did not think there was any necessity for the appointment of a committee. They had fixed the salary at £200 in the hope of getting an experienced practitioner, but now it appeared they were to have an inexperienced boy placed in charge of the hospitals in which every class of disease in its form would be found, he believed £150 a year would be a sufficient salary.

Mr. John McDonnell thought as they had advertised for candidates at a salary of £200 they were bound to pay that amount.

A poll was then taken, when 41 voted for £150, and 29 for £200.

The Chairman then read applications from the following:—Dr. Thomas Russell, Dr. Dennis McDonnell, Dr. K. O'Callaghan, Dr. Alex M'Auliffe, and Dr. Michael Taaffe.

Drs. Russell, McDonnell, and Taaffe were called in and having been informed of the reduced salary declared that they would be willing to accept it.

Dr. M'Auliffe declined to accept it.

Dr. O'Callaghan did not attend.

A poll was then taken and 39 voted for Dr. Russell, 27 for Dr. McDonnell, and 3 for Dr. Taaffe.

DUNGARVAN GUARDIANS.

ASSISTANCE IN OPERATIONS.

THE medical officer referred to an order made last board day whereby the board objected to his calling in any doctor but the union medical officers in case of a surgical operation.

Mr. Fitzgerald—I think it is throwing a great slur on our own medical officers. If they are not capable of assisting the medical officer they are not capable of being in the service of the union. Medical Officer: If the guardians had told me about it I could give them good reasons why they ought not to make that order. Mr. Fitzgerald: It is throwing a great slur—— Medical Officer: You cannot throw a slur upon a doctor. There was a very serious operation here since, and I took the whole responsibility on myself. Mr. Fitzgerald: I think in justice to our own medical officers we ought to employ them. Medical Officer: I beg your pardon——Mr. Fitzgerald (hotly): I beg your pardon, I have as good a right to make an observation here as you have. Medical Officer: If you offer me the assistance of Dr. Butcher of Dublin, I would prefer the man I had because he is young, and I could ask him to do a great many things that I could not ask another doctor. It is a very unusual thing, and I don't suppose in any hospital in Ireland the like is in force. I saw it passed here a few minutes ago, to give two guineas in a case of midwifery, and Dr. Redmond only charged two guineas for one far worse, one of amputation.

Chairman—You prefer a young man. M. O.: I prefer a young man simply because I have no hesitation in asking him to do things which I would not ask another doctor. Mr. Hackett: Is not Dr. Flynn a young man. Mr. Fitzgerald: I do not see why we should go outside our own union. I have not the slightest objection to young Redmond. He is a great friend of mine, as is also his father, but I think a great slur would be thrown. M. O.: You cannot throw a slur on a doctor. Mr. Fitzgerald: That may be your opinion, doctor, but I will have mine. Chairman: I would like to know from Mr. Boyle if it is imperative for the union medical officers to assist one another when called upon. Clerk: They are not. Mr. Terry: If they are not, they are not fit to be in the union. Chairman: I think we can only reverse this by a fourteen day's notice. Capt. Curran: This is a thing that has cropped up several times while I am here. I think it ought to be settled. M. O.: He is not under any obligation to come here unless he wishes. Mr. Fitzgerald: I think that paying the two guineas to Dr. Anthony is very absurd. If a farmer is sick a doctor will come out from town for £1. M. O.: No, Mr. Fitzgerald, he will not.

Capt. Curran—In the case of a farmer he can do what he likes, but this is a case of a public money.

Chairman—There must be fourteen day's notice to rescind it.

Capt. Curran—I won't rescind it. Mr. Terry: I won't rescind it.

Chairman—I would be in favour of granting you this doctor, but I am only one of the board, and I do not see what can be done.

Medical Officer—Will any member of the board give a notice rescinding it? Mr. Terry: I won't. M. O.: Well, I can only say you are treating your medical officer very hardly. I have done the work of this union for the last fifteen years, and I believe I done it well. I saved you expense in every way I could, and never asked for an assistant. Mr. Walsh: We are not objecting to that at all. Chairman: It is proposed that we refer the question to the Local Government Board, whether it is imperative on the medical officer of the union to assist the workhouse medical officer in case of a surgical operation. Mr. Fitzgerald said, before that was put, it would be well to have an explanation from Dr. Anthony, as to whether he refused, and if so, why he refused. If they had Dr. Anthony's version of the matter, it might be very different.

THE CLONASLEE DISPENSARY.

ON Thursday the members of the Clonaslee dispensary committee proceeded to the election of a medical officer for the district, in room of Dr. Wilkinson resigned. The election excited considerable interest in the locality. Long before the proceeding commenced a large throng gathered in the village and cheered the supporters of the popular candidate as they passed by.

The candidates for the office were Dr. Neale, and Dr. M'Kenna, Mountmellick.

Mr. Wrafter—I proposed Dr. M'Kenna as a fit and proper person to perform the duties of dispensary medical officer of this district.

Mr. Meredith—I beg to second Mr. Wrafter's proposal, that Dr. M'Kenna be appointed. I think he has a great claim on our support, *particularly because he is a Roman Catholic*, and we *want very much to have a Roman Catholic.*

Mr. Reeves—I proposed Dr. William Neale. I have listened he said with deep pain and with the greatest regret to the observations spoken by Mr. Meredith. This is the first time, and I hope it will be the last time that in an assembly of educated gentleman any allusions should be made to the question of religion. I hope and trust that a doctor of any creed, or no creed at all, will do his

duty by the people. I do not think that being a member of any particular creed, or even a Mahometan, constitutes a man a good doctor, unless he can rely on his own abilities (hear, hear.)

Dr. J. G. Peacock—I beg to second Mr. Reeve's proposition. Dr. Neale is a native of this country. His family have been always connected with the county, and he has every claim by all those rights to your support. He is known well and favourably, and every one in this room knows the members of his family, generations of whom have lived in this county.

Mr. A. Conry—Descended from the Red Hand of Ulster.

The Chairman—Order, please.

The question was then put to the vote.

For Dr. M'Kenna, 8; for Dr. Neale 9.

Dr. Neale was accordingly declared elected by a majority of 1.

When the result was announced.

Mr. Rice Meredith rose from his seat at the table, and said—I protest against the decision of this committee as being totally illegal, on account of intimidation and undue influence being used by Captain Dunne, our chairman. He sent through his tenants last night and every other day to intimidate them, and get them to vote for Dr. Neale. There is a man in this room who promised his parish priest for the last six months that he would vote for Dr. Kenna; and Captain Dunne has gone up to his house, and brought his friend with him, and intimidated him in such a way that he was afraid he would be turned out of his place if he did not vote for Dr. Neale.

Captain Dunne—I had a perfect right to ask my tenants to vote with me, if I have a friend. This is not the case of an election for the county, where politics are concerned. I have no regard for questions of religion or politics. I have nothing to say to them. All I say is, I have a right when I see other parties working day and night through my tenants—as a landlord of Ireland, I have a right to ask them to stand by me, when I stand by them.

Dr. M'Kenna—I can bear testimony to threats having been used. I have a letter in my possession by which I can prove it.

Dr. M'Kenna was about making some further observations, when the meeting broke up somewhat confusedly.

During the proceedings a large gathering congregated outside the committee-room, and on Mr. Meredith making his appearance, he was chaired through the streets amid lusty and repeated cheers. Mr. Meredith raised his hat in acknowledgment of the honour, and addressed some remarks which we did not hear.

To prevent any person getting into the committee-room but the members, two policemen were stationed at the entrance. The little village bore a holiday aspect owing to the number of people who gathered into it. There seemed to be a very strong feeling over the election, principally of a sectarian character.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF JANUARY, 1878.

JANUARY 9th.—Powell, Blacker Castles, Parkmore, Roscrea, co. Tipperary, M.B. Univ. Dub. 1877.

9th.—McDonnell, Denis, Bradford, co. Clare, Lic. R. Coll. Surg. Irel. 1877, Lic. Apoth. Hall Dub. 1878.

14th.—Sandiford, John Oldfield Greatrakes, Ballinlough, Blackrock, co. Cork, M.D. 1877 and M.Ch. 1877. Q. Univ. Irel.

14th.—Woodroffe, John FitzHenry, Lislee Glebe, Bandon, co. Cork, M.B. and Bach. Surg. Univ. Dub. 1877, Lic. Mid. K. Q. Coll. Phys. Irel. 1877.

15th.—Armstrong, Henry, Enniskillen, co. Fermanagh, Lic. R. Coll. Surg. Irel. 1877, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

22nd.—Penny, Henry James, 20 Kenilworth Road, Rathgar, co. Dublin, Lic. R. Coll. Surg. Irel. 1876, Lic. 1877 and Lic. Mid. 1877 K. Q. Coll. Phys. Irel.

23rd.—Casement, Brabazon Newcomen, The Infirmary Londonderry, M.B. Univ. Dub. 1877.

23rd.—MacNeece, Jas. Gaussen, Clonfeacle Rectory, Moy, co. Tyrone, Lic. 1877 and Lic. Mid. 1877 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1877.

24th.—Dempsey, Patrick J., Aghadowey, Ballymoney, co. Down, M.D. 1877 and M.Ch. 1876 Q. Univ. Irel.

28th.—O'Sullivan, Daniel, Tralee, co. Kerry, Lic. 1877 and Lic. Mid. 1877 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel, 1877.

28th.—Fergusson, Edward, 32 Upper Rathmines, co. Down, Lic. R. Coll. Surg. Irel. 1874, Lic. 1876 and Lic. Mid. 1876 K. Q. Coll. Phy. Irel.

29th.—O'Donnell, Joseph Francis, Longford, M.B. 1877 and B. Surg. Univ. Dub. 1877.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING JAN. 26, 1878.

Total registered deaths in Dublin and suburbs*			177
Ten years average of same week			199
Decrease of mortality below average			22
10 weeks ratio of deaths Rathmines		19·7 per	1,000
" " " " Donnybrook†		26.9	"
" " " " Blackrock		19·5	"
" " " " Kingstown		14·9	"
" " Entire Dublin District		29·3	"
COMPARATIVE RATIOS—London		27·2	"
" " Glasgow		26·6	"
" " Edinburgh		24·1	"

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 22; being 9 less than in the preceding week, and 15 under the average for the fourth week of the last ten years. The deaths from these diseases include 4 from small-pox—those of a male infant seven weeks old, and 3 men, aged respectively 24, 33, and 45 years, *none of whom had been vaccinated;* two of the men were admitted into Cork Street Hospital from Peter Street District, and the third was received into the same institution from Meath Street District; all three died from the confluent type of the disease; the child died in the Hardwicke Hospital, into which he had been admitted from Coleraine Street District. Among the remaining deaths from zymotic diseases are 3 from fever (2 typhoid or enteric, and 1 simple continued fever), 3 from measles—being 8 less than in the preceding week—3 from scarlet fever, 2 from whooping-cough, 1 each from diphtheria croup &c.

Thirteen children died from convulsions.

Deaths from diseases of the respiratory organs, which, in the preceding five weeks had been respectively 48, 38, 59, 56, and 34, rose again last week to 49, of which 35 were attributed to bronchitis 10 to pneumonia, 1 to asthma, and 3 to lung disease unspecified. The deaths from these causes do not quite equal the average mortality in the fourth week of the last ten years.

Heart disease caused 6 deaths, aneurism 1, paralysis 7, apoplexy 2, epilepsy 3, brain disease unspecified 2, liver disease 1, Bright's disease 2, and kidney disease unspecified 1.

Twenty-four deaths resulted from phthisis, 4 from hydrocephalus, and 1 from mesenteric disease.

BELFAST.—Four deaths from fever, 5 from diarrhœa, and 1 each from scarlatina, measles, and whooping-cough were registered during the week.

CORK.—Three deaths from measles, and 1 each from fever and diarrhœa were registered.

YEARLY SUMMARY—1877.

BIRTHS.

DURING the year 1877 there were registered in the

Dublin District 9,325 births, being a ratio of 30 per 1,000 of the population. The average for the preceding ten years was 28 per 1,000.

Of the births, 31 in every 1,000 of the population occurred in the city, and only 24 in every 1,000 inhabitants in the suburban districts.

In London the ratio of births registered during the year was 36 in every 1,000; in Glasgow, 38 per 1,000; and in Edinburgh, 33 per 1,000.

DEATHS.

8,795 deaths were registered in the Dublin District during the year, being equal to 28·0 in every 1,000, against an average of 26·1 per 1,000 for the previous ten years.

Omitting 328 deaths, which are those of persons admitted into public institutions from localities outside the Dublin District, the death-rate for last year is 26·9 per 1,000 of the population, the rate for the city being 28·7 per 1,000 (28·3 on the North side and 29·1 on the South), and for the suburbs 20·4 per 1,000 The rates for the several districts range from 19·2, the rate for Rathmines, to 36·3. Meath Street District.

The deaths registered in Belfast during the year afford a ratio of 28 in every 1,000, in Cork 26, in Limerick 25, in Londonderry 19, in Waterford 22, in Galway 23, and in Sligo 22.

The deaths in London during the year 1877 amounted to 22 in every 1,000; in Glasgow to 25 per 1,000; and in Edinburgh 21 in every 1,000.

DISEASES.

Dublin Registration District.—Compared with the average annual number in the preceding ten years, there was a decrease last year in the mortality from zymotic diseases, and an increase in the deaths tabulated under each of the four other classes into which the causes of death are grouped, the chief excess being in the mortality from diseases of the respiratory organs.

The deaths from all diseases of the zymotic class registered during the year number 1,528, or 48·6 in every 10,000 of the population, being somewhat over the mortality from these causes in either of the two years preceding, but 218 deaths, or 7 per 10,000 persons under the annual average for the ten years 1867-76. Nearly 60 per cent. of the deaths from zymotic diseases last year occurred amongst children under five years of age. The deaths from the seven principal diseases of this class, exclusive of the deaths of persons from without the district who died in public institutions, are equal to 3·7 per 1,000 inhabitants, the rate for the city being 4·1 per 1,000, the rates varying from 2·8 per 1,000 persons in Denzille Street and Grand Canal Street District, to 5·8 in Meath Street District, and for the suburbs 2·3 per 1,000, the lowest suburban zymotic rate being 1·8 per 1,000 in Donnybrook, and the highest 3·4 in Blackrock.

Nearly one-third of the total mortality from zymotic diseases was caused by measles and its complications, the deaths from which amounted to 481, 1·5 per 1,000 inhabitants, as against an average rate of 0·4 per 1,000 for the preceding ten years, in none of which except the first (1867) did the deaths from measles equal one-half of the number in last year; in 1867, and the coincidence is remarkable, the number was 405. Forty-six of the deaths tabulated under this heading last year were registered in the first quarter, 146 in the second, 122 in the third, and 147 in the fourth.

There were 38 deaths from small-pox registered—viz., 33 in the city, 2 in the suburbs, and 8 hospital cases admitted from other districts.

Fever caused 280 deaths, of which 74 were classed as from typhus, 153 from typhoid, and 53 from simple continued fever. The average annual number of deaths from fever in the ten years 1867-76 was 318; in the year 1876 the number was 260.

Among the remaining deaths from zymotic diseases are 122 from scarlet fever (the smallest number in any year since 1866, and only one-third of the average annual number for the ten years 1867-76), 23 from diphtheria, 29 from erysipelas, 106 from whooping-cough, 101 from croup, 9 from quinsy, 156 from diarrhœa (being 111 under the average), 17 from dysentery, &c.

The deaths attributed to convulsions number 629, being 7 per cent. of the deaths from all causes. In 1876 the number was 594, and in 1875 it was 566. The deaths entered under this heading last year are exclusively those of children, and with 9 exceptions, were amongst those under 5 years of age.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 87.)

HEREDITARY SYPHILIS.

Concerning the heredity of syphilis, I think no practitioner at the present day is inclined to doubt that syphilis can be conveyed to the fœtus either through the male germ, or from the mother at any period during pregnancy, or at any stage of the disease. Yet it is of interest to note that the existence of substantive changes in the brain and nervous system, resulting from a transmitted taint, was not fully appreciated until within the last few years. In fact, the first case duly recorded in this country was by Dr. Barlow, in the Pathological Society's "Transactions" for 1877. Graefe some years ago described the case of a child less than two years old, in which a syphilitic new formation was found on two cerebral nerves (*Archiv für Ophthal. I. Bd.* 1 *Abth*), and Dr. Hughlings Jackson drew the attention of the profession to this subject in the *Journal of Mental Science*, 1875. The first clear case which came under my own observation was in the year 1874, and is here reported. It is doubtless a thoroughly genuine one of gummata of the brain and nerves, from congenital syphilis. Probably, before long, thanks to the investigations of Heubner, it will be found that many of the conditions which are now recognised as scrofulous, are really due to albuminoid or protoplasmic nutritive changes, the result of arterio-capillary constriction which originated in syphilis. In due time, evidence will probably be forthcoming to show that these changes also occur in the lymphatic system, and that they are coexistent with the primitive states of fœtal life. If pathology is not leading us astray, our deductions at the present time are of the greatest value and importance. The signs of hereditary syphilis, apart from the manner in which it invades the nervous system, have been so carefully studied and elucidated by Mr. Hutchinson, that it seems mere repetition either to examine or question them. There can be no doubt that his observations are usually received by the profession as conclusive evidence of the existence of the hereditary poison. Yet, it has often occurred to me in the examination of a large number of children, many of whom I have known to be syphilised, that if we confine ourselves merely to the consideration of the cupped incisor teeth of the upper jaw, and an interstitial inflammation of the cornea, we shall not always be using our judgment aright, and we shall, probably, make an incorrect diagnosis. I certainly maintain that we are not in a position to state that dental irregularity, apart from notching, means scrofula, whilst on the other hand, I have no wish to doubt that the especial signs referred to by Mr. Hutchinson, are indicative of syphilis.

I have seen the so-called scrofulous development of the head and jaw, irregular and regular notched teeth, to be the essential outcome of hereditary syphilis, and I have likewise seen them where no syphilitic taint could be detected, and this I know to have been the experience of a very large number of observers.

There is no man living who is sufficiently presumptuous to say that there are no cases to be found where it is not a matter of questionable certainty as to the condition being one of scrofula or syphilis. How often do we not see this statement verified in daily practice by the result of treatment? Our little patients have all the signs indicative of scrofula. They are wasted, ill-developed, rickety; with enlarged abdomen, large cranial development, pinched features, prominent under jaw, thick lips, irregular teeth, some notched, others serrated, squat nose, corneal opacities, congestion of the coats of the eye, and retinal exudations, hair fine and scant, ears large, spine distorted, ulcerations of the skin and mucous membrane, intermittent diarrhœa, and enlarged cervical glands. But withal the intellect may be clear.

I put the question, Do we invariably find these patients

improve upon the administration of so-called anti-scrofulous treatment, such, for instance, as cod-liver oil, the various preparations of steel, the dilute mineral acids, and chlorate of potash? I cannot say in my own experience that this has been the case, but a small quantity of grey powder every night, with iodide of potassium during the day, acts like a charm. Get the iron bond of taint broken through, and the normal nutritive processes rehabilitated, and then the cod-liver oil and steel not only do an infinite amount of good, but effect an absolute cure. Such then, being admitted, I will go a step farther and candidly say that in my own opinion, scrofula is essentially the outcome of syphilis; and I believe such has been the opinion of many other observers. M. Ricord and Mr. Erasmus Wilson, have put forward similar views. If we take the history of syphilis from the earliest time up to the present day, and allow ourselves to be guided by general facts; if we are not blind to the evidence which pathology can and does afford us; if we are not too sceptical of the deductions drawn from the effects of treatment, I feel sure that the growing weight of proof will be found in favour of this view.

Should there be a point in pathology of greater interest than any other, it is not so much the difference in structure between gummatous, scrofulous, or amyloid growths, as the association which often exists between them and their prime factor, syphilis. In the discussion on syphilis at the Pathological Society of London, in 1876, Sir James Paget, during his remarks, said: "I would not venture to call the disease that may occur in a scrofulous person become syphilitic, a hybrid one—and yet, perhaps, the term is not altogether wrong—but at least I would call it a mixed disease, and hold that syphilis, inserted in a scrofulous person, will in its tertiary form produce signs which it may be very hard to distinguish from scrofula. Signs in which the character of scrofula and of syphilis are mingled, and—which is very important—which require that the treatment of scrofula should be combined with the treatment of syphilis, in order to produce a fully successful result." From this statement, which does not, I must admit, support my opinion in any but an indirect way, provided it is true, that a scrofulous person contracts syphilis, and in the later stages of the disease such person suffers from a hybrid or mixed disease, which is neither scrofula or syphilis, but partakes alike of both, what effect does this hybrid condition produce upon the offspring of the parents so infected. Do we get scrofula mingled with syphilis, and syphilis mingled with scrofula; or have we, on the other hand, a distinct and novel entity established, which I conclude we must have, if the words of Sir James Paget are correct. At any rate it must be extremely difficult to say what condition may result from this hybridity, presumably the result of syphilis engrafted upon scrofula.

These three kinds of growth, Gumma, Scrofula, and Amyloidea, are more intimately associated in their nature than those of any other kind, and are merely the result of low inflammatory exudation changes, guided by a specific agency. They may be said to be a perversion of Nature's nutritive laws and selective capacity; and we can, I think, fairly well comprehend, how in children, particularly those born of intemperate parents, the subjects of syphilis, we find a state of tissue, that is of mucous nerve and other vascular textures, which is not normal, and where the controlling power of the vascular and trophic nerves is first at fault; and then secondly the blood participates, resulting in every form of low inflammatory change, which may of course determine the abnormal growths which we meet with in the teeth, the eyes, the skin, nates, and viscera. In the last volume of the Pathological Society's "Transactions," 1877, I was much interested to find a case of congenital syphilis (the one to which I previously referred as reported by Dr. Barlow) involving the cranial nerves and cerebral arteries, and he frankly states that the syphilitic nature of the disease was not diagnosed during life, but tubercle was suspected. The child was a boy aged fifteen months. We are led to conclude that the little patient had no signs of syphilis beyond those stated in the paper, namely, a sore bottom and frequent discharge from the nose. However, at the *post-mortem* examination made by himself and Dr. Lees, evidences of syphilitic infiltration were abundant in the nerves and vessels. He says the nerves were very extraordinary. "Both thirds at their superficial origin were swollen out into small conical tumours. There were also swellings in the fourth, fifth, sixth, seventh, and eighth pair, causing considerable broadening of these nerves. There was very little difference on the two sides in bulk, though I presume there must have been a different amount of change in the two facial nerves, for example, from the clinical differences which were observed. I have examined, microscopically, the third and fifth on one side. The first thing that strikes one is the almost entire atrophy of the nerve cylinders. Here and there in some of the sections are round bodies resembling corpora amylacea (altered myalin?). There is a most abundant infiltration of new cells with very fine stroma. This new growth is by no means most abundant in the interfunicular areolar tissue. It is, in fact, less abundant there than in the interfuniculi themselves, though it is to be noted that in the funiculi generally there is more of it at the periphery than in the centre." Dr. Barlow then goes on to describe the changes in the vessels, which resemble those first described by Prof. Heubner, and which I shall again refer to when speaking of the pathology of my own case. I have rather lengthily referred to the pathology of this case, because it is certainly of some interest from a clinical and of great importance from a pathological point of view; and it is rendered most complete by some well-executed microscopic drawings. The following case is of more extended pathological interest.

This woodcut shows very well the palsy of the *right* sixth and of the *left* seventh nerves, and the scars about the nose, with deformity.

G. D., a fairly-well nourished girl, æt. 12, was admitted into the Central London Sick Asylum, at Highgate, under my care on the 12th November, 1874. She was one of four living children, none of whom were healthy. The father was a strong healthy man; he contracted syphilis when young. The mother was said to have died of phthisis and to have had several miscarriages; she gave birth to seven children. The history is as follows: Her health was delicate as a baby, and continually so until she was five years of age, when the eyes became inflamed, and there was an offensive discharge from the nostrils. She was then placed under treatment, and her health improved. In the year 1872, she had a fit, and was unconscious for four hours. When consciousness returned she was violently sick.

The next thing which ailed her was an ulceration about the alæ of the nose, resembling a tubercular syphilide.

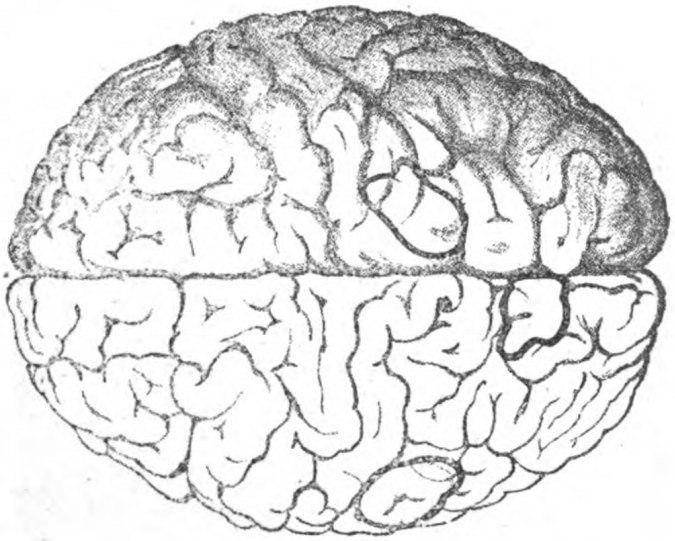
The ulcers were deep, of rapid formation, and attended with pain.

Around tha ulcerated surfaces there were numerous papular or tubercular elevations causing an indurated condition of the skin, the whole being of a reddish colour shading off into the surrounding cuticle. The discharge was extremely offensive, and encrustations were rapidly shed and reformed. After the ulceration had completely invaded and destroyed the soft structures at the tip of the nose cicatrisation set in, and the ulcerative process in this respect was completely stopped. (*a*) After, and almost coincident with the healing of the nose (and this is an extremely interesting point) she began to suffer from severe pains in the head, which became worse towards night; she described them as dull and aching; they were confined more particularly to the sides and back of the head. Then followed a series of epileptic seizures, which were associated with mental and visual derangement. Upon one occasion she went into a room without any fire and persisted in saying that it was full of smoke. At the time that she came permanently under my care her facial expression might be called hideous.

In the first place there was deformity of the nose and complete absence of the sense of smell, an offensive discharge coming from the nostrils. 2. There was double vision, and, upon ophthalmoscopic examination, the discs were seen to be hazy and their margins ill-defined; the arteries were contracted and the veins seemed of normal size. There was a paleness with some pigment spots upon the choroid. The left eye was remarkably immobile, the pupil dilated, and the whole of the globe was partially anæsthetic, the conjunctival and sclerotic vessels were intensely congested and dilated from vaso-motor paresis. The cornea was slightly opaque, not centrally, but toward the upper half. The third and fourth nerves of the right eye were not involved. There was marked anæsthesia of the left half of the face and hyperæsthesia of the right half. The right sixth nerve was palsied. The left seventh nerve was completely palsied from disease of its trunk, and all the signs of this condition were present. The bulbar nerves were not involved beyond those just mentioned. There was no absolute muscular palsy or paralysis of the extremities beyond a feeling of weakness. The voice was weak, but the vocal cords acted freely; the teeth were regular and presented none of the appearances usually attributed to hereditary syphilis. There was otorrhœa, with sanguinolent discharge from both ears. For days together she would lie in a state of partial stupor, apparently careless of all about her. At other times she was so giddy that she was unable to walk across the ward without reeling, and then again she would have a series of epileptic seizures; these were associated with screaming and violence, not preceding the fit, but afterwards as consciousness was returning. The aura commenced in the left arm and ended in the tongue, as though a number of needles were pricking it. During the violence of the fit there was the most rigid muscular spasm; the right side was more convulsed than the left. Towards the close of her life she became aphasic, and said "Yes" and "No" to everything. At this time there was a partial paralysis of the right side. The sphincters were competent, but the normal mental attributes were wanting. Urine free from albumen and sugar. She died during an epileptic fit.

The *post-mortem* examination was made some eighteen hours after death. Upon removing the skull it was found to be of normal thickness and free from erosion. The dura mater was easily removed from the surface of the anterior lobes, but, when the parietal lobes were reached, strong adhesions were found to exist in each cerebral hemisphere.

On the right side the growth was about the size of a shilling, and occupied the upper part of the superior parietal lobule. On the left side two distinct growths were found, one of which was seated upon the postero-parietal lobule, and the other upon the gyrus supra-marginalis. These growths were of like character, of a pinkish tinge, and firmly adherent to the dura mater, of which they appeared to form part, and from which they originated. They did not dip deeply into the brain substance, for their thickness was not greater than that of a two-shilling piece.



This woodcut shows the seats of the gummata as found in the brain upon the superior parietal lobule, the postero-parietal lobule, and upon the Gyrus supramarginalis.

Upon microscopic examination, they were seen to be made up of the elements of a gumma without apparently having undergone any degeneration. In addition to these growths, the surface of the brain, in contiguity to them, had undergone softening, and was of a yellowish-grey colour; the pia mater generally was deeply injected, and there was chronic arachnitis with effusion.

When the base of the brain was exposed, the vessels were seen to have an appearance similar to what we find from acquired syphilis. These were thickened, of a whitish colour, and semi-opaque; they remained open and gaping when cut through, like one sees in atheroma and advanced fibrosis.

But upon microscopical examination the change which they had undergone was found to be quite dissimilar from either, and corresponded exactly with Heubner's description, which is now so well known and fully recognised. The lumen of the vessels was seen in some places to be nearly occluded by an accumulation of spindle-shaped cells between the tunica fenestra and the epithelial lining; and interspersed with these, but particularly in the muscular and adventitious coats, were to be seen an enormous quantity of a round-celled growth, which in many parts seemed to actually replace the normal structures. The nerves were not examined microscopically, but the left, fifth and seventh nerves were thickened, swollen, and of a tough but gelatinous character.

I have no doubt that if these nerves had been examined under the microscope, they would have presented the same appearance which has been described by Dr. Barlow. I regret very much also that the lenticular ganglion of the left orbit was not examined, as we might have found some changes to account for the peculiar features presented by the left eyeball. Nothing abnormal was detected in the thorax. Upon opening the abdomen the liver was seen to be considerably enlarged. It weighed six pounds eight ounces, and from its position must have exercised some upward pressure upon the contents of the thorax. It was pale, and gave the mahogany red reaction with iodine indicative of amyloid infiltration. The kidneys were large, pale, and amyloid. The mesen-

(*a*) See case by the author in Clinical Society's "Transactions," vol. x., Case xxxviii., "On a Fatal Case of Syphilis contracted from the Hereditary Form of the Disease."

teric glands were of normal size and appearance. I have given this case somewhat in detail because it is unique, and with the exception of Dr. Barlow's, none other has been reported in this country.

(To be continued.)

Hornsey Lane, W.

THE ORIGIN OF POSTERIOR STAPHYLOMA AND THE MECHANISM OF SHORT-SIGHTEDNESS.

(Analysis of a Communication made by DR. LORING, *of New York, to the Philadelphia Medical Congress.)*

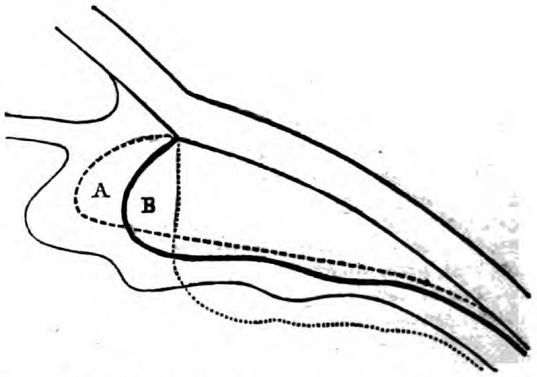
By ARCHIBALD H. JACOB, M.D. DUB., F.R.C.S.I.,
Formerly Ophthalmic Surgeon to the City of Dublin Hospital, and to the Dublin Eye and Ear Infirmary.

ARE progressive myopia and conus (posterior staphyloma) due to hereditary predisposition, or can they be induced by defect of refraction acting through the influence of the ciliary muscle? This is the question asked by Mr. Loring, of New York, in a recent pamphlet, and the conclusion arrived at by his inquires are :—1. That hereditary predisposition, though undoubtedly a potent cause, is not only not the sole cause, but not even the predominating cause of progressive myopia; and (2), that the action of the ciliary muscle taken of itself, exerts but little influence on the production of myopia, and still less on the formation of the cone.

Having reference to the almost universal opinion as to the heredity of short-sightedness held by past authors, and even by Stellwag Von Carrion, Jæger, Donders, and other lights of the present day, Dr. Loring expresses surprise that no writer in any language has attempted to sustain the theory by precise statistics. Dr. Loring tabulated the condition of 715 persons, and found "that the per-centage of those who had normal eyes themselves, but whose parents were myopic, was nearly identical with the per-centage of those who not only were myopic themselves, but who had myopic parents. That is to say, that the per-centage of emmetropic children from myopic parents was as high as that of myopic children from myopic parents." In corroboration of his impression that myopia and heredity are not essentially connected he quotes Cohn, who finds that only 2·7 per cent. of the myopes examined by him had one parent, and only 1·04 of them both parents myopic. Dr. Loring's analogous figures were 6·11 and 1·11 per cent., which proportions, he says, "do not show a marked hereditary tendency or warrant the expression of so decided an opinion" by authors.

If, in any case, it can be shown that an anatomical formation is peculiar to a certain disease, the presumption is that it is congenital as a rule, and the earlier it shows itself the more likely it is to be hereditary. Now these conditions are fulfilled by myopia, and almost all authors are agreed that posterior staphyloma is due to congenital malformation, and is not the result of any change during life. Graefe even said that, in myopia of one-sixth to one-half, ninety per cent. showed the existence of posterior staphyloma, and he thought that the proportion was really nearer one hundred per cent. than this. Nevertheless, Dr. Loring deprecates the idea that posterior staphyloma and myopia are synonymous. He, himself, found in 500 (aged 6 to 21) myopic eyes, only 20·5 per cent. posteriorly staphylomatous. Cohn, and Max Conrad, in 1,000 similar cases each, found only 20·0 and 28·1, presenting the "crescent" which is pathognomonic of posterior staphyloma. Dr. Loring, moreover, makes the remarkable assertion that of his own cases, only one-fourth showed any change whatever, while there were three-fourths of the eyes which showed no deviation from the normal standard. He also states that posterior staphyloma is by no means confined to myopes; for in 2,265 of his cases in which it was observable, 3·33 per cent. had normal eyes, 3·49 per cent. had hypermetropic eyes, and 20·56 per cent. myopic eyes. He furthermore refers to the great scarcity of conus in new-born children, and its development in eyes which, by previous examination, had been ascertained free from the defect; and he, therefore, maintains that myopia and the existence of the "crescent" are not, as much as has been believed, the result of congenital posterior bulging of the sclera, but are developed in after life from other causes.

The second anatomical variation, which is supposed to be characteristic of the myopic eye, and one which has had great importance attached to it, is the peculiar conformation of the ciliary muscle, which is supposed to be congenital. This condition was specially investigated by Iwanoff, who produced the following representation of the muscle in three typical eyes.



CONDITION OF THE CILIARY MUSCLE IN LONG SIGHT, NATURAL SIGHT, AND SHORT SIGHT.

Thick dark line shows section of ciliary muscle in emmetropic or normal eye.
Broken line - - - - - - - - - - - - - - in hypermetropic or far-sighted eye.
Dotted line ..... in myopic or near-sighted eye.

The hypermetropic muscle, it will be observed, is more bulky than that of the emmetropic eye by the mass of the triangle *A*, and the myopic muscle less bulky by the amount of the triangle *B*, and, moreover, extends further backwards along the sclera. The circular fibres of the muscle, are in all cases, situated at the thick end of the muscle next the lens, and Iwanoff's theory is that they are deficient in the myopic eye, and increased in the hypermetropic eye, merely from their disuse in one and constant employment in the other condition, the accommodative effort being constantly required in the latter and very seldom in the former. It was further shown by Iwanoff, that the longitudinal fibres had become hypertrophied in the myopic eye, as the circular had atrophied, and that thus the muscle had come to act simply as a "tensor choroideæ" acting solely from before backwards, and ceasing to draw towards the axis of the eye.

Dr. Loring's theory is, that the altered condition of the muscle is not the result of any accommodative effort or want of effort, but arises from intra-ocular distension, which forces backward the posterior part of the globe, and this drags upon the longitudinal fibres and flattens the thick circular portion of the muscle, which condition, he considers, would also account for the fact that the lens is flatter in high degrees of myopia than in the normal eye, and thus he restricts the hereditary tendency to a transmitted disposition to weakness of sclera, and looks upon intra-ocular distension as the motive power in the production of posterior staphyloma and of the ciliary changes. If, he says, analogous distension may cause the inguinal ring to yield, and expand the pleura or peritoneum, "why may not similar yielding, which is myopia, take place when the growing and elastic membrane is subjected to over use?"

Dr. Loring finds that this theory obliges him to prove the existence of progressive myopia and posterior staphyloma in perfectly emmetropic eyes which are not influenced by heredity, and even in hypermetropic eyes which are influenced in the opposite direction. There is considerable diversity of opinion as to the existence of this latter case, for Donders denies its occurrence, while Jæger and Stell-

wag state that such cases occasionally present themselves. Dr. Loring endeavours to establish the existence in the fully developed emmetropic and hypermetropic eye of such results of the alleged distension, and, to do so, he quotes statistics collected by Erismann in Russia, Max Conrad in Germany, and Dr. H. Derby and himself in America. The examinations were all of the eyes of school children aged 6 to 21, all degrees of refraction being included, and in the American cases being submitted at the same time to the ophthalmoscope. Erismann's cases numbered 4,358; Conrad's, 3,036; and Derby and Loring's, 2,265, making in all 9,659 patients. The results of these examinations are tabulated in diagramatic form, and the following conclusions may be superficially deduced from them :—

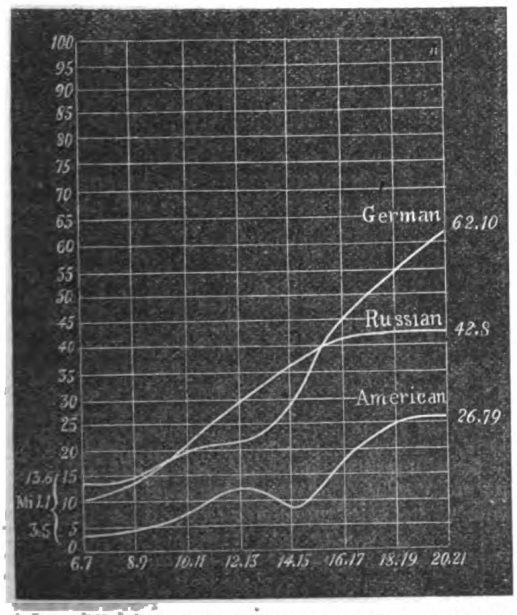
1. In Russia and Germany there is a marked decrease in the per-centage number of hypermetropes, as children advanced in age, *i.e.*, hypermetropia is rapidly lost from 6 years old to 21, the loss being more frequent in Russia than in Germany in the proportion of 31 to 9.

2. In America this is not so, for the hypermetropia increases slightly.

3. At the same ages myopia becomes developed in all countries, the increase in the number of myope school children being—in Russia, 39·2 per cent.; in Germany, 51·0 per cent.; and in America, 23·24 per cent.

4. In Russia and Germany thus it may be said that the *average* school child becomes less and less hypermetropic until he or she reaches the age of about thirteen, when the eye is normal or emmetropic, and then begins to become myopic, in which condition it advances. In America, however, the greater number of eyes are emmetropic in the first instance, and remain so until twenty-one; while of those which do undergo alteration, the hypermetropia does not pass the line of normal refraction and commence to become myopic until about seventeen years of age.

The progress of short-sightedness in the three countries is thus found to be very different, and a comparison between them is important. The following diagram gives the three curves of myopia side by side. The figures at the left side are the per-centages of children affected, and those at the bottom the ages at which they are affected.



CURVES, SHOWING DEVELOPMENT OF MYOPIA IN VARIOUS COUNTRIES.

An examination of these curves is instructive as regards natural differences in the development of myopia.

In Germany the number of myopes between 6 and 7 years of age is 13·6 per cent. of all school children—a greater percentage than in either Russia or America. Up to 11 years of age many children develop short-sightedness, and the percentage of myopes at 11 is 21·0. From 11 to 14 years of age few children become myopic, but from that age until 21 the short-sightedness affects a large number, so that at 21 years of age 62·1 per cent. of all school pupils are near-sighted.

In Russia the early development of myopia is nearly equally marked. Eleven per cent. of all school children between 6 and 7 years old are short-sighted, and from that age until 21 there is a certain steady increase in the number of those affected, but that increase is (42·8) nearly 20 per cent. less than in Germany. In America a very much smaller number of school children (3·5 per cent.) are myopic at 7 years old, and the development of the short-sightedness does not much increase until the children reach 15 years of age, after which the number of myopes rapidly advances. Not much more than a fourth (26·79 per cent.) of the American school children ever become myopic—a marked difference from Germany, where yearly two-thirds (62·10 per cent.) are short-sighted at 21 years of age.

It is thus very thoroughly proved that a usual progression of the eye in youth, when subjected to prolonged accommodative effort, is from hypermetropia to emmetropia, and thence to confirmed myopia; and the question now arises as to the cause of such change. Is it the chronic contraction of the ciliary muscle? There are two ways by which the ciliary muscle could render an eye, previously not near-sighted, myopic. The first would be by increasing the curvature of the lens, and the second by producing elongation of the antero-posterior axis of the eye. That such an increase of curvature of the lens does occur temporarily during near vision is now all but universally admitted, and the writers of the last generation held unanimously that that curvature might, and did, by persistence, become permanent, and that, in fact, the lens of a myope was always of the curvature suited to near objects. This impression has been conclusively disproved by Helmholtz, Donders, and Knapp, who showed that, if anything, the myope lens was usually flatter than the normal. Though this increased curvature may not be the sole or principal cause of acquired myopia, Jæger and Stellwag, nevertheless, assert very positively that it is a cause, and commonly an active cause. That increased curvature of the lens does not necessarily result from prolonged ciliary tension, may be concluded from the fact that the hypermetropia of young persons often does not cure itself, but that such patients frequently need to increase the strength of their glasses as they go on in life. Dr. Loring considers that such facts as these warrant us in the belief that, as a rule, the action of the ciliary muscle has no effect in producing a permanent increase of the curvature of the lens, and thus becoming a cause of myopia. He also considers that the theory of elongation of the eye-ball as a result of prolonged tension of the ciliary muscle, has been negatively disposed of by Young, and Helmholtz, and he argues, with much force, that, if traction on the choroid by the ciliary muscle could produce posterior staphyloma, that condition would be most frequent where the traction was greatest, *i.e.*, in hypermetropic eyes, yet every observer knows that this is not the case. It is also evident that, if the cone were produced by the ciliary strain, the yielding of the sclera (of which the "crescent" is the observable sign) would occur at the place where the strain was greatest, *i.e.*, to the inside of the papilla, which we know is usually the reverse of the case. Dr. Loring expresses, in fact, his disbelief in the theory that the ciliary muscle exercises any pull upon the posterior pole of the eye, and he doubts that it can produce any effective strain even upon the anterior part of the choroid.

Having thus dealt with the prevalent theory as to the production of posterior staphyloma, Dr. Loring proceeds to state his own theory, *i.e.*, "that the enforced and maintained contraction of the ciliary muscle produces that nervous exhaustion and irritation, with altered nutrition, which

always occurs in the case of an overtaxed muscle. That this irritation extends to the surrounding parts, causing increased vascularity and increased secretion." He "is, however, inclined to believe that this increased intra-ocular pressure, which is so potent a factor in the production of myopia, occurs much more frequently from other causes, especially from faulty convergence."

He states his conclusions from the whole investigation in the following words :—

1. "From the fact that there is so large a per-centage of children who are myopic, but whose parents are not near-sighted, while the myopia increases greatly with the amount of increased tension of the eyes, and from the fact that an interchange of refraction may occur, whereby an eye which is not congenitally myopic may become so in spite of hereditary tendency, it would seem to follow that hereditary predisposition, though undoubtedly a potent cause, is not only not the sole cause, but is not even the predominating cause of myopia.

2. "The action of the ciliary muscle, taken by itself, exerts but little influence on the production of myopia, and still less upon the formation of the cone."

Dr. Loring does not enter further upon the causes of myopia. It seems to me that he has made no attempt to prove that the distension or intra-ocular pressure with which he credits the formation of conus really exists as an essential concomitant of that condition. If he expresses disbelief in other possible causes, he should be able to show that the cause which he assigns is invariably present. In my experience myopes do not generally present the usual signs of intra-ocular tension. Perhaps the degree of tension which Dr. Loring supposes is less than that distinguishable by touch or by other usual means, and must, if so, be assumed, but not proved, but it is difficult to conceive that a degree of increased tension so slight as to be inappreciable to the senses, could produce so extensive a bulging of the sclera as that which exists with myopia. Moreover, our experience of intra-ocular tension, and its results upon the eye, are directly at variance with Dr. Loring's theory, for we have seen that small degrees of over secretion within the eye-ball, in the early stages of glaucoma, do not produce myopia, but hypermetropia, no matter how long such condition continues, and we know that when that tension does affect the ocular tunics, it is not the sclera, but the optic nerve which first yields to compression. If Dr. Loring's theory of the origin of posterior staphyloma were correct, we should have it in every case in which prolonged, though slight, intra-ocular tension, and a thinned sclera came together. Experience tells us that this is not so.

23 Ely Place, Dublin.

Clinical Records.

NATIONAL ORTHOPÆDIC HOSPITAL OF IRELAND.

Cases under the care of Mr. LAMBERT H. ORMSBY, F.R.C.S.,

Surgeon to the Hospital, and to the Meath Hospital and Co. Dublin Infirmary.

Reported by Mr. ARMITAGE FORBES.

CASE I.—*Double Talipes Varus (Congenital).*

PATRICK M., æt. 6, suffering from double talipes varus, 3rd degree. Was admitted into this hospital from Co. Carlow, under Mr. Ormsby's care on the 20th November, 1877.

History.—Was the child of a poor widow who had four other children, who were all born healthy, and well made. No history of maternal impression or otherwise. She never applied to any medical man for treatment.

State on Admission.—The boy, a fine healthy little fellow in appearance, walks on the outside of the feet, with a very hobbling gait, provisional bursa developed all along the outside of the foot, owing to pressure. The plantar fascia in each foot much contracted.

Operation performed on November 24th, by Mr. Ormsby, who divided the tendons of the tibialis, posticus, and auticus muscles, and plantar fascia, with a tenotome, in each foot. A small metallic splint adjusted with a bandage, and then a plaster of paris bandage applied, and before the plaster set, the feet were held with the hand in a forced position, so as to simulate equinus. The plaster was allowed to set, and then the foot remained so with the adduction completely corrected. This position was maintained with the plaster of paris for 6 weeks, when the plaster was removed, and the tendo-achillis in each foot was divided, and a pair of "Stromeyer's foot boards" applied, which acts remarkably well in cases of talipes equinus.

CASE II.—*Single Talipes Varus (Congenital).*

Patrick Dunne, æt. 8, was admitted to the hospital from Co. Kildare, suffering from single talipes varus of the left foot, 2nd degree.

History.—When the child was young, the parents had the child in a large hospital, and treatment was adopted, tendons divided, &c., but the case relapsed, and the boy walked on the outside of the foot, and not on the sole. Bursæ, as in the proceeding case, were developed on the outside of the foot. The tendons in the same order were divided, and the plaster of paris bandage applied, and the child, who has been three months under treatment, now walks with the sole flat on the ground.

CASE III.—*Double Talipes Varus (Congenital).*

James Kennedy, æt. 2, was admitted on July 3, with his mother, from Co. Limerick, suffering from double talipes varus.

History.—The mother states that when the child was a few months old, she came to Dublin, and had the necessary treatment applied. The tendons were divided, but when she returned home to the country, the case relapsed as bad as ever.

State on Admission.—The child, a healthy little fellow, when placed on the ground, stood on the outside of the feet; the plantar fascia considerably contracted.

Treatment.—It was found necessary to divide the tendons again, and in the same order as before. The mother directed to constantly manipulate the feet with her hands, so as to correct the adduction and extension present.

Boots with a mechanical ratchet pivot suggested, and the child was discharged on the 1st September, 1877, walking on the soles of the feet. Since that time, the case has been heard of, and no relapse has occurred.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

THE Fourth Meeting of the session was held on Friday evening, January 18, 1878; the Vice-President of the College, Mr. P. C. SMYLY, in the Chair.

(*Continued from our last.*)

THE DEATH OF DR. WILLIAM STOKES.

Mr. EDWARD HAMILTON said :—I have been asked to undertake a duty which I am sure every member of the Society will assist me to discharge with solemn enthusiasm; for it is a duty which I think the Surgical Society of Ireland would not be true to itself if it did not discharge. This Society is eminently intended to be a Society for the promotion of the progress of medical science in its widest acceptation; and I would ask the Society now to express the sense of sorrow and regret which it must naturally feel, individually and collectively, at the loss of one of the great pioneers of science in this country—the late Dr. William Stokes. That name, Sir, requires no lengthy panegyric from me, nor shall I attempt to undertake such a task. But I hope and I trust that the story of his eventful life

will be written by some one competent to do it, for the benefit of mankind, and as an example to his professional brethren. In this assembly of surgeons and physicians, seeking out the onward and advanced paths of science, the name of William Stokes needs no eulogium, and I would say, in the words of the author, "*Si monumentum queris circumspice.*" I do not allude to monuments of bronze or of marble, but I do allude to that fame which will ever surround the name of our great Irish physician. Who is there in this room—not many, I would say—that has not learnt something from William Stokes? It may be when, as pupils, you have hung on those words of dignified eloquence with which he clothed his clinical teaching; it may be as students that you culled the golden corn of scientific truth from his published writings; it may be at the bedside of the sick that, in the hour of difficulty and doubt, you have summoned to your aid that master mind to unfathom the hidden mysteries of obscure disease. We all know, at such a time, with what chivalry he used to discharge such duties; we all know that there was no egotism, no self-glorification; no word of his, no hint of his—I would even say, no thought of his—ever breathed the slightest shadow of a cloud on the reputation of a professional brother, however humble or however juvenile he might be. With these few words, I would ask you to permit me to put the following resolution to the meeting:—

"That this Society hereby records its deep sorrow and regret at the loss which it, as well as the profession at large, has sustained by the death of their illustrious and distinguished associate, Dr. Stokes; and the members take this opportunity to tender to his sorrowing family their condolence and heartfelt sympathy while they mourn the loss of an affectionate father, a sterling friend, and a truly accomplished physician."

Mr. Rawdon Macnamara:—Mr. President,—Probably as the son of the oldest friend that Dr. Stokes had, and as —I say it in the humblest terms—one who had the great privilege of being, not only in the commencement of his career his pupil, but as his career advanced his colleague, I feel a melancholy satisfaction in seconding that resolution. I feel, on behalf of the family of Dr. Stokes and of his relations and admirers, that their thanks are due for the very kind and appreciative language in which the resolution has been moved by my friend Mr. Hamilton, and I feel still more the appreciative manner in which it has been received by this distinguished Society. The very last occasion—not very long ago—upon which Dr. Stokes attended a meeting of this Society was one when a question of great importance to the community at large, and of great interest to himself, was under discussion—it was the question of the propagation of fever. We all remember how kindly he attended upon that occasion, with what earnest enthusiasm he entered into the question; but I feel myself, with my friend Mr. Hamilton, that this is not the occasion, this is not the time, nor probably is either of us the person to pronounce his *éloge*. His *éloge* is written in a life of honour, a life of service to his profession, a life of generous devotion to the interests—more so to the interests of others than his own; and when I heard my friend Mr. Hamilton state that the thought even of disparaging a professional brother never entered his mind, it came strongly across my mind that the thought of self-advancement, of self-elevation, of self-praise, of claiming for himself that which was so justly due to him, never crossed his mind. I believe a more earnest, truthful, conscientious labourer in the cause of science, in the cause of truth, and, for the sake of science, of truth alone, never breathed than my venerated master and colleague, William Stokes; and I feel very proud of this Society that on this the first occasion of our meeting since his demise, we have not omitted to avail ourselves of the opportunity of expressing the sentiments of each person present here to-night, however feebly they may have been expressed.

Dr. Benson: As perhaps the oldest member of the profession in this hall to-night, and as one who almost from Dr. Stokes's infancy—from I may say his boyhood—intimately acquainted with him, I can vouch for the truth and accuracy of the encomiums which have been passed upon him. I never knew a more honourable man in the practice of his profession than he was, and one of the earliest experiences I had of that was in a case in which I was myself engaged. It was soon after he came over from Edinburgh. I was but a short time practising in Dublin at the time, and had very few cases to attend to, but in the case to which I allude, I was greatly interested. His name had just been acquired with regard to the practice of the stethoscope, and he was called in to see this case, but the moment he learned it was a patient of mine, he declined to attend without consulting me; and though strongly urged by the patient, he steadfastly adhered to his determination. All his life he only attended to his own particular line, and was a model of correctness in the profession. As to his authority in medicine, it would be useless here to speak of it—it is world wide. I was anxious to say that as an old friend, and I may say, a companion of his for the last fifty or sixty years, I can vouch for the correctness and amiability of his conduct, and for the truly professional style in which he always practised.

The Vice-President: I have now to put to the meeting this resolution, which has been so eloquently proposed by Mr. Hamilton, and so ably seconded by Mr. Rawdon Macnamara, and so appropriately spoken to by my dear old friend Dr. Benson. The state of my feelings prevents me from saying anything on the subject of the resolution. Dr. Stokes, from the time I was a boy was my dearest friend, as he was my father's dearest friend, and I can never forget how Dr. Stokes wept when my father died, for he was attending him.

The resolution was then put and agreed to in solemn silence.

EXOSTOSIS OF LOWER JAW.

Dr. Barton exhibited an example of exostosis of the lower jaw. It was removed from a young woman, æt. 17. It had existed for four years, and she could not give any account of injury. The teeth were in a perfect state of preservation, and the jaw was free from caries or other irritation. It grew very gradually, and she could not state that it had taken on any recent rapid action, but for four years it gradually increased. It was not the seat of any pain, but what was rather unusual, it presented, as one of the photographs which he exhibited would show, several cicatrices over its back surface, and these followed upon small abscesses, which had formed apparently in consequence of some local irritation. They were very small, but caused those puckered scars and adhesion of the skin over the tumour. It was not necessary to attempt, even if it had been possible, to remove the tumour through the mouth. The scars left it quite possible to make the incision an external one, and the tumour was easily laid bare. What he now exhibited was not the whole tumour, but the largest portion. About a quarter of an inch was afterwards removed with a saw. An inspection of the specimen showed that it belonged to the class of ivory exostoses. Its extreme hardness presented considerable difficulty in the removal.

EXCISION OF ELBOW FOR ANCHYLOSIS.

Mr. Tyrrell stated that some time ago a girl from the co. Galway came to the Mater Misericordia Hospital, and stated that a year since she suffered from an injury about her elbow. She went to a neighbouring bone-setter, who straightened her arm, put it up in splints, and left it so for a considerable time, she believed about a month. When the splints were removed the arm was found to be stiff and perfectly straight. She then, on the advice of some local surgeons whom she consulted, came to Dublin, and put herself under his (Mr. Tyrrell's) care. On examining the arm he found that the elbow was perfectly anchylosed, and although he put her under the influence of ether to the fullest extent, he could make no impression upon the joint. He therefore determined to excise the elbow. He found it an extremely difficult operation, very much more difficult than would be the case in operating for disease. On a former occasion he read a paper before the Society in which he stated that the best way to avoid the ulnar nerve was by not looking for it, because during his six previous operations he had not seen the nerve. However, on the present occasion, the nerve was found bound tightly down to the bone; it was only owing to the greatest possible care, and also to being very slow about the operation, that he was able to avoid the nerve. However, he succeeded in not injuring that important nerve. On examining the specimen which he now exhibited, it would be perceived that the cartilage was removed from the olecranon process, and

the ulnar nerve was displaced backwards, with a T-shaped fracture extending into the joint, which fracture was partly united, the union not being osseous, but fibrous. The only point of interest to which he wished to draw the attention of the Society, was rather that he wished to modify the opinion he expressed on a former occasion—that they need not in all cases look for the ulnar nerve. Now he would say that in the case of excision of the elbow-joint for injury and subsequent anchylosis, that they should look for it, and be very careful about it. In cases of excision for disease, when they were able to peel off the soft parts they were liable to raise up the nerve with those soft parts. That was not the place for him to allude to the subsequent treatment of the case, but he would simply say that he put up the limb in the straight position for a fortnight, then let the arm fall into its place, and he was happy to say that the patient, though it was but a comparatively short time—three weeks—since the operation was performed, had now almost perfectly recovered.

OVARIAN CYST.

Dr. LOMBE ATTHILL said the specimen which he now exhibited was a very interesting one if it were only as an example of the amount of disease which might exist compatibly with life. It was an ovarian cyst which had been removed by him from a patient in the Rotunda Hospital about ten days since. The existence of ovarian cystic disease in this patient was diagnosed some five or six years ago, and the operation as a cure suggested. The patient would not, however, submit to the operation. She was tapped several times, but at that moment he was not exactly able to say how often. He saw the patient for the first time in consultation about May last. At that time the abdomen was of enormous size. The existence of a large ovarian cyst was perfectly certain, as was also that of a certain amount of ascites. He then advised immediate operation, but she would not consent. Tapping again afforded temporary relief, and he neither saw nor heard more of her from that time until about a fortnight since, when he was sent for urgently and with a message to the effect that he was to bring the largest trochar he had. When he arrived he found the poor woman propped up in bed, breathing with much difficulty, and in great pain. Her medical attendant told him that he had tapped her three or four times since he (Dr. Atthill) saw her in May, and that prior to each tapping she had suffered from immense pain. After each tapping she evidently was the subject of a certain amount of peritonitis, the symptoms being of a tolerably severe character, but that relief was always for a time obtained. He had endeavoured to tap her again on the day before he (Dr. Atthill) was called to see her, but had only removed a very small quantity of lymph, the trocar, which was one of the ordinary size, becoming blocked up by large masses of lymph which got into it before the exit of the fluid, which it was utterly unable to get away except to the extent of a few pints. The symptoms were in no degree relieved by that tapping, and the friends of the woman now urged that he (Dr. Atthill) should tap her with a very large trochar. That proceeding he objected to. He felt that to tap her with a large trochar would be very nearly as dangerous as to perform the operation of ovariotomy, even though it might not succeed, and even though it gave only temporary relief. He therefore told her friends that he would not tap her, but that if they wished it he would perform ovariotomy, telling them at the same time that the result of that operation was extremely doubtful; that he could not advise such a course otherwise than as a last resource, as the patient was evidently dying. She had not slept for many weeks, and she could not breathe except in the semi-erect position, and she constantly rejected food, even lime-water and milk. Evidently she could last only a few days, and he thought that possibly the operation might save life, or at least prolong it. After some hesitation the friends of the patient consented. He had her brought to the Rotunda Hospital, and so eager were the friends then for the operation that they wanted it performed on the day she entered the hospital, and insisted on its being done on the next day, before any opportunity had been afforded, so to speak of putting the patient in a fit state for the operation. Under those unfavourable circumstances he performed the operation, Mr. Fitzgibbon kindly using the carbolic spray, which answered uncommonly well. The abdomen was of enormous size, measuring forty-eight inches. There was a considerable amount of fat over the walls of the abdomen, and on cutting down through that they found it impossible to distinguish between the peritoneum and the cyst; the peritoneum was so immensely thickened by repeated attacks of inflammation, and so intimately adherent to the tumour, that anything like separation of the cyst and the peritoneum was almost impossible. After making a number of vain efforts to separate them, he made a large opening in the abdomen, allowed the sanguineous fluid to escape, passed his hand into the abdomen, and gradually brought out the mass, which he now exhibited. The operation lasted an hour and ten minutes. Having taken out the tumour with a great deal of difficulty, they could then find no pedicle. He ligatured three distinct processes, but which was the pedicle he was uncertain. A careful *post-mortem* examination had not satisfied them as to that yet, but he intended to make a further examination. Although the poor woman was in a dying state—indeed he thought she would have died of exhaustion under the operation—she, however, rallied a little, but the reaction soon set in, and she died. The specimen was remarkable in this important point, among other things, that it contained a large amount of bony matter. He with great difficulty escaped tearing his hand, in consequence of the extreme sharpness of this bony matter. He had not had it examined carefully yet, but it gave one the idea of a fœtal bone. It occurred to him that it might originally have been one of those remarkable cysts which had been met with, and which contained bony matter and hairs, and so forth. As he had before said, the cyst had not as yet been carefully examined. It was greatly reduced in size, because it had been out of the body ten days. The patient died the third or fourth day after the operation. The *post-mortem* examination, carefully made, had not added to their knowledge. The parts were so completely disintegrated by repeated attacks of peritonitis, that they could not make out the remaining ovary. The uterus was reduced to an exceedingly small size, probably owing to a process of atrophy. The patient was a married woman, had had a large family, but had ceased to menstruate for five or six years.

CEDAR PENCIL REMOVED FROM THE GLUTÆAL REGION.

Mr. TYRRELL said that when he was the other day going round the wards of the Mater Misericordiæ Hospital, his attention was called to a young man who had just come from the South of Ireland. On asking the patient as to the nature of his injury, he stated that he had been sent up to Dublin for treatment, as it was supposed that he had broken off a portion of the great trochanter. He inquired from the patient how the accident happened, and he was informed that he was the owner of a country shop, and that he had fallen down about a dozen steps of stairs in his own house, while in a state of intoxication. On examination he (Mr. Tyrrell) found immediately below the trochanter a small wound suppurating, and on pressing the part he found a foreign body beneath his fingers. He enlarged the incision, and drew out with a dressing forceps an ordinary lead pencil about nine inches in length, and then of course the cause of the injury was at once cleared up. It appeared that the patient carried the pencil in his breeches pocket, and that in falling downstairs it penetrated the glutæal region. After the pencil had been removed, the patient, who was much surprised, got up, put on his clothes, and went home by the next train.

APPLICATION OF FLETCHER'S BLOWER TO DOCTOR PAQUELIN'S THERMO-CAUTERE.

By B. WILLS RICHARDSON.

Having on various occasions felt inconvenience in working with the hand the double-bag bellows (of Dr. Richardson of London) attached to Dr. Paquelin's Thermo-cautère, I was led to consult Mr. Long, of Messrs. Yeates,' on the advisability of substituting a Fletcher's bellows for the caoutchouc bags. Being worked with the foot the Fletcher's bellows leaves to the surgeon the use of both hands for an operation, a matter of no small moment when assistants are scarce. Mr. Long took the matter in hand, and found that none of the large Fletcher's bellows in his possession, although specially constructed to work the spray producer he (Mr. Richardson) described in the number of the *Dublin Journal*

of Medical Science of December, 1876, had sufficient power to drive the air and benzoline vapour to the platinum cauteries. Mr. Richardson now worked the spray producer alluded to, that the Society might see the large volume of spray it is capable of producing, and yet its large bellows would not act satisfactorily with the thermo-cautère. It was found by experiment, that the Fletcher's bellows necessary for prolonged and efficient action of the cautery should give a pressure of 4 lbs. to the square inch, whereas the bellows of the spray producer, to produce even the largest volume of spray, gives a pressure of only 2½ lbs. to the square inch. Finally, Mr. Fletcher was communicated with, who accordingly constructed for me a bellows of the power mentioned. Although smaller than the bellows of the spray producer, it nearly doubles it in power. Mr. Richardson finally observed that Fletcher's bellows had other advantages over the caoutchouc bags. For example it is, with ordinary care, but little liable to get out of order, and when the caoutchouc requires renewal, which it ought not to do for a considerable time, the surgeon can himself easily replace it. The caoutchouc bags, on the other hand, frequently get deranged, and when they stiffen for want of use, are liable to be spoiled, if not heated equally in the attempt to restore their pliancy. Mr. Richardson now worked the thermo-cautère with Fletcher's bellows, the platinum being immediately raised to an intense heat, at which it was maintained while the supply of benzoline lasted.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
ND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM

Chapter IX.—Preventive Measures.

(*Continued from page* 115.)

3. If it is only a suspicious case it is well not to kill it immediately, but to keep it confined and under close surveillance, so as to be able to verify the true state of the animal's health. If the animal should be rabid, then it must be killed and buried.

4. If an animal suspected of or affected with the disease escapes from its owner, or from a locality, or if an animal of this description is seen in a locality, the police should be immediately warned. They, in their turn, should, without causing alarm or fear, instruct the public, and warn them; under such circumstances, all children should be watched, and dogs and other animals ought to be confined and kept from strange dogs. All wandering dogs should be confined or killed. Every means must be adopted, with due precautions, to capture the mad or suspected animal. If really rabid it should be killed. If only suspected its life may be spared, in order to ascertain its true condition.

This is all the more necessary if anyone has been bitten, for if the animal is healthy the person bitten is relieved from the terror and mental suspense generally experienced by those in that condition. The period during which it should be kept under observation, should certainly not be less than four months.

In every case, and under all circumstances, the local authority should take exact note of these occurrences, and particularly endeavour to discover the domicile and the owner of the animal, and learn whether any person or animal has been attacked or wounded by it in the locality or elsewhere, as mad dogs run great distances, especially at night, the regulations and restrictions should be applied over a wide extent of country, and neighbouring districts should be warned. Hertwig tells us that he has observed that dogs belonging to peasants or persons living in the country, and running at large without supervision into the towns, were the chief instruments in the extension of the scourge. The announcement made to the inhabitants of the surrounding districts should mention the country towards which the animal is probably proceeding, or the direction from which it came, and a description should be published of the animal with regard to breed, size, colour, and other distinctive characteristics. A register should be kept containing the names of owners of dogs, with the number of animals they keep, their sex, and purpose for which they are kept; all sales, transfers, exchanges, or deaths must be duly notified to the authorities. When muzzles are worn it is above all things necessary that it should fit the dog's head in such a manner that it cannot bite through it or slip it off. A muzzle too small is most objectionable, as it may irritate the animal, and cause it great discomfort, while one too large may allow the dog to inflict wounds. If the wearing of muzzles is ordered the police should see that every dog has one of proper size, and any wilful infraction of this most essential regulation should be punishable by a fine.

The destruction of dogs must be carried out assiduously. No dogs should be allowed to be at large, and all stray dogs should be caught and killed immediately if without a muzzle; but if at large with a muzzle on they might be kept for three days; if wearing a collar with the owner's address they might be returned and a fine imposed. In all cases neglect of the sanitary orders should be severely punished. All dogs bitten by those which are mad or suspected, or which have been in immediate contact with them, should be destroyed, or sequestrated for a proper period. It is certainly a painful proceeding to kill all suspected animals, for the dog is a creature to which man is attached by a sentiment of affection, frequently of the strongest kind; to many it is the favourite of the family, especially of the children, and often a cherished *souvenir*. Our better feelings and admiration for the most affectionate and devoted of animals would not prompt this *dernier resort*, but for the dreadful character of rabies, and the great danger to which the human species and other creatures might be exposed by leniency. The value of the dog is too small, and the danger too great, to admit of any exception being made. Experienced men ought to be employed in capturing and destroying animals. When captured they should be gently dealt with and all cruelty should be studiously avoided. They ought not to be lead or dragged along, but put into a covered cart or waggon, with separate compartments for each animal, to prevent fighting and subsequent danger, for if put together in one place it might happen that a rabid dog might be among the number, and wound the others, some of which might be claimed by their owners and set at liberty again. Life should be extinguished as promptly as possible, the avoidance of pain being studiously inculcated. Science offers us the choice of efficient poisons, as certain narcotic vapours—chloroform, bichloride of methylene, &c., but nothing can be more effective and humane than the administration of strong *newly-prepared* prussic acid. Instruments must occasionally be used, when poison cannot be obtained.

We do not conceal from ourselves that numerous difficulties oppose themselves to the application of one or other of these measures, but they are nevertheless absolutely necessary, and if applied with vigour would ultimately bring about the total extinction of the rabific contagion. Sequestration is only too frequently an uncertain measure, while immediate slaughter of suspected animals is, for the people, a condition of absolute security. We believe that humanity points out the course to be adopted. It is better that dogs should die than mankind. If the sentiment of humanity does not speak loud enough to inspire and cause to be followed by everyone the line of conduct above indicated as the best, there is an excellent means for determining the owners of suspected dogs to sacrifice them, that is, to make the responsibility for the damage and disaster their animals may cause weigh heavily upon them.

Disinfection.

All the slaughtered dogs should be buried in a place set apart for the purpose, and at a good depth, the skins should not be removed from their bodies, but should have large cuts made crossways in them, and they ought never to be thrown into ditches, ponds or streams, as is so frequently done. All the wood-work, straw, shavings in connection with kennels should be burnt or thoroughly soaked with carbolic acid, Condy's fluid, or some other powerful disinfectant.

The floor of the kennel, stable, or place in which the animal has been kept should be well scrubbed with boiling water, and covered with quick-lime, or any agent noted for its power in destroying contagious matter.

The same should be done with the walls of the place as high as the dog could reach. The chain that attached the animal, and other ironwork which may have been in contact with it, should be heated in the fire, and all necessary precautions

adopted, as in diseases which are communicable by a fixed or even volatile contagium.

With reference to disinfection, it may be worth referring to Hertwig's experiments. After giving a number of dogs the saliva and blood of rabid animals without result, he put five of them into kennels where mad dogs had been, put the collars of these upon their necks, attached them by the same chains, made them lie down upon the same straw, but yet none of them became rabid.

Duration of Police Regulations.

With regard to the length of time during which the police regulations should r main in force, there is no definite rule. Knowing the limit of the period of incubation, it might be inferred that the sequestration of dogs should extend to that period. In Saxony, where the dog-laws have been rigidly carried out, it has been found that three months was generally an effective interval, though, if new cases occurred during this time the period was dated from them. Notwithstanding the inconvenience and annoyance oftentimes occasioned by the restrictions imposed for so long a period, yet those who suffer most from them should bear in mind the great interests that are at stake, and cheerfully aid the authorities in their endeavour to suppress a contagion which causes such terrible destruction and alarm; the more strictly judiciously-framed veterinary police regulations are obeyed, the sooner will the course of the pestilence be terminated, and the less will its ravages be felt. The same police regulations are applicable to rabid cats—they ought to be at once killed, and all other dogs or cats bitten by them destroyed.

Measures to be Adopted with Other Animals than Dogs.

We have already made some allusion to the measures to be adopted with the other domesticated animals, and we have now to complete our observations. In the last century, and perhaps even now—for in this country there are no veterinary police regulations for this disease—the same severe measures were sometimes applied to other domesticated animals as to the suspected dog, through ignorance of the disease as it affects them, as well as indiscrimination, and they were generally killed at once or left to chance, as the case might be. In dealing with them it must be remembered that they are not like the dog, our constant companion, and that their natural weapons of attack are different, so that they very rarely extend the contagion; and, in reality, veterinary police regulations should have chiefly for their object the health of the animal while alive, and its destruction when diseased. When these animals have been in contact with or bitten by a rabid or suspected dog the circumstance should be reported; they should be visited by an expert as quickly as possible, and their bodies carefully examined, particularly the ears, mouth, and nose, the limbs, and tail, in order to discover if there are any wounds, even of the most trivial description. Those discovered to be wounded should be at once isolated and carefully watched. Preservative treatment may be recommended, but, of course, cannot be ordered. Haubner states that the isolation of wounded animals is unnecessary, as nothing is to be feared from them should they become mad. Röll says separation and medical treatment is necessary unless the proprietor decides to kill them. But, as will be seen from our previous description of the symptoms, all rabid animals, including the dog, cat, fox, and wolf, of course are more or less dangerous to others, or to mankind, and particularly the horse; even the sheep may become so at times. It is better, therefore, to separate the suspected from the uncontaminated, and to place them under veterinary or police observation.

Such animals as horses, oxen and other beasts of labour should be permitted to work in the immediate vicinity of their homes, but they ought not be allowed to travel far beyond this on any pretext. If a mad dog has been among a herd of cattle or flock of sheep the whole herd or flock should be placed under surveillance.

None of the domesticated animals, other than those referred to, if bitten or suspected, should be sold, bartered, or removed within a period equal to the limits of their several periods of incubation.

Röll gives four months for the sale of horses and cattle, but for other animals used as food the minimum may be three months.

Haubner gives the period of supervision as two months for sheep, three months for pigs and horses, and six months for cattle, and we should prefer this as a basis for regulating the restriction to that of Röll. At any rate, it is a great mistake to make the quarantine the same for all animals; this should be regulated by the average duration of the incubatory period in the different species. The immediate slaughter of all the bitten animals is unjustifiable, as only about 50 per cent. take the disease, and, when compared with dogs, the danger is very trifling, even when rabies manifests itself. It is, therefore, time enough to resort to slaughter, when the disease shows itself, unless the owner is desirous of avoiding the risk of loss, and wishes to sell the carcase for food.

As soon as the disease manifests itself, notice ought to be given to the authorities, and an examination made by a veterinary surgeon, when, if it be ascertained that rabies is really present, and the owner does not object, the animal may be killed. All animals in which rabies is confirmed should be slaughtered, and no attempt at treatment permitted except under the restrictions before mentioned.

The carcase must be buried intact, with the skin slashed profusely. Haubner admits that if with rigor mortis the virulence of the contagium is extinct, then skinning might be allowed if conducted with care, and the skins utilised. Should the carcase chance to be dug up and eaten by animals there is no danger to be apprehended, according to Haubner; but Lafosse says the dead bodies should be covered by at least four feet of earth, and the burial places guarded from carnivorous creatures.

Disinfection.

Everything used with rabid animals was at one time destroyed, but neither observations nor experiment, as we have shown, warrant such a measure. The same means of purification may be resorted to as have been prescribed for the dog.

The Flesh as Food.

Haubner says that the slaughter of animals for food may be permitted within twenty-four hours after the bite of a rabid creature, but the injured portion must be cut out and destroyed. Even after this time killing an animal for the sake of its flesh may also be permissible, provided the flesh be consumed by the owner, and not offered for public sale; as the sentiment of the consumers must be consulted.

Milk.

According to the same high authority, forbidding the use of milk derived from bitten animals is wrong until the disease appears. It may be given to other animals, and the owner of the cattle might use it. Butter and cheese might also be made from it until it was ascertained whether or not the animal had been successfully inoculated with the rabid virus.

People have remained healthy, even when using the milk at the commencement of the disease, but our researches prove that both flesh and milk are dangerous when the malady is developed.

Résumé of Preventive Measures.

The measures to be recommended for the prevention of rabies and its extension to the human species may be comprised under the following heads:—

A. The owners of dogs and other animals should be made to understand the responsibility that rests upon them with regard to the health of their animals, particularly when contagious diseases appear among them.

B. The number of useless dogs should be diminished as much as possible, and a tax should be levied on all dogs.

C. Every dog should wear a collar with owner's name and address engraved thereon, as well as a particular mark impressed by the licensing or police authorities, for the proper registration and identification of the animal.

D. All stray dogs without the collar or the owners name and address thereon should be captured, and, if not claimed within a limited period, sold or destroyed; and dogs straying with the proper collar on may, where circumstances render it necessary, be seized and confined or returned to the owner, who pays expenses and is fined if need be. Bitches in *rut* should not be allowed to go at large at any time.

E. Unless under special circumstances, as when rabies is prevalent, or when certain animals are vicious, the muzzle should not be worn.

F. The owners of dogs should be held responsible for the damage done by them.

G. Diseased dogs, or those which show the slightest symptoms of disease—altered habits, &c.—should be carefully watched, and precautions adopted. If the symptoms of rabies appear the circumstances should be reported to the police by the owner or attendant on the dog, or other persons who know of its condition. Neglect of this should be estimated as

a criminal offence. The police should know the early symptoms of the disease.

H. If other animals which have been in contact with or bitten by a rabid dog become unwell afterwards, the symptoms ought to be noticed, and should they lead to a suspicion of rabies the creatures must be isolated, and their condition reported to the police.

I. Suspected animals should not be killed at once if they have bitten any person, but only destroyed when the disease is unmistakably present.

J. A mad or suspected dog escaping from its owner, or appearing in a district, should be the signal for alertness, and those who know of the circumstance ought to warn the police at once. Children should be guarded and animals confined or kept from strange dogs. All wandering dogs should be confined or killed.

K. Rabid dogs should be killed, or, if suspected, they may be kept until their condition is ascertained.

L. The police authorities should endeavour to obtain every information about any rabid or suspected dog, and to discover the name and address of its owner, learning also what damage it may have done. Regulations and restrictions should be extended over a wide space of country, and neighbouring districts should be warned. All information necessary to put the inhabitants on the alert ought also to be given.

M. When the disease appears in a virulent or epizootic form, all measures ought to be rigorously enforced. Owners of dogs should give due notice of all changes occurring among their animals. Muzzling may be necessary, but the muzzle for each dog should be properly and securely constructed, and sufficient in size without being too large. It must have appliances for attaching it firmly to the head.

N. The destruction and confinement of dogs must be assiduously carried out, and heavy fines or imprisonment should be imposed upon those who attempt to evade or neglect the regulations.

O. Dogs should be slaughtered with as little cruelty as possible. They ought to be buried deeply in the ground.

P. Disinfection should be carried out as with other contagious diseases.

Q. The police regulations and restrictions should be continued for some months beyond the appearance of the last case of rabies. This period should be dependent on the limit of the incubatory stage of the disease in the dog.

R. With regard to other animals when wounded by a suspected or rabid dog, the circumstance should be reported, and steps taken to ensure safety. Horses, oxen, and other working animals, may be employed in the immediate vicinity of their homes, but must not be sold, bartered, or removed within a certain period. The immediate slaughter of wounded or suspected animals is not necessary, but as soon as rabies manifests itself notice should be given to the local authorities, and the necessary steps taken to prevent damage. The bodies should be buried intact, though, under special circumstances skinning them may be allowed, in order to tan or dress these parts.

S. Disinfection to be resorted to as in the case of rabid dogs.

T. The flesh is not dangerous as food until the symptoms of the disease have appeared. If used before this period certain precautions should be adopted.

V. The milk may also be utilized during the same period.

X. Competent veterinarians must co-operate in the execution of these measures.

QUALIFICATIONS OF PUBLIC MEDICAL OFFICERS.

THE Bill, of which the following is an abstract, has been introduced by Messrs. Errington, Maitland, and Blennerhasset, M.P.

Whereas it is expedient to amend the law with reference to the qualifications required for holding certain medical appointments, and for registration under the Medical Act (1858):

Be it enacted, &c. :—

1. Clause fifteen of the Medical Act shall be and is hereby amended so far as it permits persons to be registered who are possessed of only one qualification described in Schedule A. of said Act; and from and after the passing of this Act no person shall be entitled to be registered under the provisions of the Act unless he possesses a degree or license to practise medicine as well as a degree or license to practise surgery from some university or college or other body duly authorised to grant the same.

2. *From and after January 1st.*, 1879, clause thirty-six of said Act shall be and is hereby amended as follows: No person shall hold any appointment as a physician, surgeon, or other medical officer in the military or naval service, unless he be registered under this Act; and no person shall hold any appointment as a physician, surgeon, or other medical officer in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union, or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity or old age, nor as a medical officer of health, unless he be registered under this Act, and unless, in addition to being so registered, he shall also have been examined and declared competent for such appointments by an examining board to be constituted as herein-after provided.

3. Within a period of *three months* after the passing of this Act the General Medical Council shall appoint an examining board, consisting of *three* examiners from England, *three* from Ireland, and *three* from Scotland, whose duty it shall be to examine all persons who, being already duly registered under the Medical Act, shall present themselves for examination, and who, on passing such examination, shall be entitled to append to their names on the General Medical Register the letters C.M.B., signifying the Civil Medical Board, and shall be eligible to hold public appointments as provided in clause two of this Act.

5. The Board of Examiners so appointed shall be a purel examining board, and shall have no power to inquire into or lay down courses of education or study.

6. The fee for examination and certificate from the examining board shall not exceed *five pounds*, and in case the amount so received for such examinations and certificates should not be sufficient to defray the salaries and expenses of the examining board, *it shall be lawful for the Lords Commissioners of the Treasury to award such sums as may be necessary for the purpose.*

7. The examinations shall take place at the times and places to be fixed by the General Medical Council.

8. The examiners shall be appointed to hold office for *three* years; they shall not be eligible for re-election for three years after their retirement; members of the General Medical Council shall not be eligible to be appointed as examiners.

The Bill, it will be seen, provides :—

1. That every practitioner *must* be registered.

2. That every practitioner must have a double diploma.

3. That every public medical officer must pass a state medical examination in addition to his license examination.

It is hardly necessary to discuss the measure seriously, as it has not the least chance of adoption either by the Medical Council, the Government, Parliament, or the profession.

DR. LUTON, of Rheims, states that the tincture of iodine in distilled cherry-laurel water is a far more efficacious and innocuous means of treatment in the purulent ophthalmia of infants than the nitrate of silver. One gramme of the tincture may be added to twenty grammes of the water of medium strength (20 deg.), and produces a collyrium the colour of pale brandy. Some of this should be dropped into the eye four or five times a day, external lotions being also abundantly employed. It has proved rapidly successful at the Hotel-Dieu of Rheims.

THE fifty-seventh annual court of the Seamen's Hospital Society was held in London last week, the report showing favourable results notwithstanding the general depression of the past year,

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 13, 1878.

THE FUTURE OF THE ENGLISH CONJOINT BOARD.

THE success or failure of the conjoint scheme cannot be a matter of indifference to all those who are anxious to see an improvement in the standard of medical education, and the establishment of a more perfect and uniform system of examination. The principle involved in the division of labour may be a good one, and has certainly been of incalculable advantage as respects the achievement of various industrial pursuits, and the general order and well being of the working portion of the community, but it is a very questionable guide when the object aimed at is to supply the public with men who are in every respect competent not only to cure or prevent disease, but to maintain that dignity of behaviour, and that character for skill and scientific acquirements which should be claimed for every gentleman in the medical profession. That no fewer than 19 licensing bodies should have been entrusted with the very responsible task of granting licenses to practice medicine and surgery, and that the examinations of many of these bodies should have been either very imperfect, or very deficient as respects the standard of knowledge required of the candidate, all this has been long a legitimate aspersion upon the educational portion of the medical profession. Nor can we be surprised that a more uniform and perfect system of pass examination has been called for by the all but unanimous voice of the medical public in this country, and that there is not perhaps a half-dozen of either teachers or medical practitioners who would deny that the present movement is a step in the right direction.

We are, therefore, pleased to hear that the authorities who are responsible for the due introduction of the One-Portal System are doing all in their power to make it *un fait accompli*, and to ensure its success. The great corporations have voluntarily and most willingly come forward to attain an object which has long been desired, and to set an example which, it is to be hoped, will be followed throughout the United Kingdom. They are unanimous as to the chief principles on which the Board should be based, and many of the details by which the new system is to be practically carried out, while the fact that they are all satisfied with the share they are to respectively take in the constitution of the Board and the conduct of the examinations, may prevent one cause of jealousy or complaint interfering with the general harmony of their work. The Committee of Reference are, at the present time holding frequent sittings, and they have already settled many details as respects the number of examiners on each subject to be delegated by the corporations respectively, the subjects on which the candidate shall be examined, the places where the different portions of the examination shall be conducted, and other detail, the publication of which would be now premature.

Seeing that the One-Portal System, as far as England is concerned, is soon to be put on its trial, and that it is one in which the student also must be taken into account, it may be as well to glance at some of the obstacles that may prevent the Conjoint Board answering the sanguine expectations formed of it, and to see how these obstacles may be best removed or avoided.

There may be, for a time, a certain want of harmony and a certain amount of confusion inseparable from the first coming together of different bodies of men who have hitherto acted independently of each other, and with different objects in view. But we do not think that this confusion or discord will last long, and at all events, we feel certain that no feeling of jealousy or of discontent, will mar the mutual co-operation of those liberal-minded men who will direct, or actually conduct, the examinations of the Board. Of more importance to the immediate success of the new Board will be the character and standard of its examinations. If they are too lenient, they may act as a decoy for those students who might otherwise feel inclined to do without the conjoint license, but they would then not only lower the Board in the estimation of the profession and the public, but would be defeating one of its principal objects, namely, the establishment of an uniform, a perfect, and a practical standard of examination. This mistake, however, is not likely to be committed. The Board is far more likely to err in the other direction and to make its examinations too difficult. It will have to be borne in mind that, after all, the examination of the Conjoint Board will be a minimum pass examination, and that if its standard is raised too high, the Board will forfeit that popularity which is so essential to the success of most reforms, and the student will be driven to enter the profession, or at least to practise, on more easy terms. As every one knows, the great bulk of medical practitioners have hitherto been licensed to practise by a body of examiners who, being themselves engaged in general practice, could best estimate the contingencies of general practice, as well as the kind and amount of knowledge

which should be demanded of those who were about to follow in the same path. The value they put upon the collateral sciences and the more theoretical parts of medicine was in proportion to the practical application of these science to the every day duties of the general practitioner, and was not exaggerated by that enthusiasm and bias which every specialist feels for that particular science to the study of which he has devoted a great portion of his life. Somewhat different will be the relationship between most of the Conjoint Board examiners and the candidates who come before them. The learned physician may dwell too much upon some obscure points in pathology, or upon some questionable doctrine of the day, to the neglect of that practical knowledge and those little details of practice with which every medical man should be familiar. The chemical expert may think too much of the mysteries of the alcohols, and other subjects of advanced or theoretical chemistry, forgetting that the candidate is not going to be a chemist, but a practitioner in medicine. These errors will have to be guarded against, particularly as, for a long time to come, the operation of the new scheme will be confined to this country, as it will be still longer before the law will compel every student to pass the Board, and as, moreover, it is not desirable, through the unnecessary severity of the examinations, to prejudice the mind of the candidate against a system of examination which may eventually prove to be one of the most important and successful medical reforms of the present day.

It is, indeed, no slight drawback to the future success of the Conjoint Board that for some years it will be optional to the student whether he passes it or not, and that the licensing bodies of Scotland and Ireland will still be open to him. The Scotch and Irish bodies are not likely to follow the example set them by the English board until they see how the new system works, and, in the meantime, they will continue to give their inferior or imperfect licence to all who, either through ignorance or the undue severity of the English examinations, are induced to appear before them. Thus many of the evils inseparable from a competition of this kind will still remain. Consequently, it may be impossible for the Conjoint Board to at once raise their examinations to so high a standard as might be desirable, and in that case they would not have so much influence as they ought to have in raising the general standard of medical education.

There is one principle which should mould the examinations of these conjoint boards—namely, that they should exact from the candidate a thorough knowledge of the main principles and facts of each subject on which he is examined; and that such examinations should be as consistent as possible with the method of education at present pursued at the schools, and with the opportunities which the student has had of acquiring the knowledge demanded of him. This principle will be the more imperative the more compulsory the examinations are made, and especially if the conjoint scheme is adopted in each division of the United Kingdom. One circumstance to which attention has lately been drawn will show the propriety of acting upon this principle. The enormous number of unqualified medical practitioners in this country has been frequently animadverted on in the pages of this journal, and recently the Registrar-General has called attention to the large number of cases in which the causes of death are uncertified, and to the fact that this evil arises in a great measure from the number of unqualified men who are in practice either on their own account, or as assistants. Thus, in one place, the whole of the medical practice was conducted by two unqualified assistants of the practitioner who resided at a distance, and who held the appointment of Poor-law medical officer. Now, it is evident that if this state of things exists at a time when there are several examining bodies, whose license may be obtained on pretty easy terms, the evil may be aggravated if the candidate for a license is compelled both in England, Scotland, and Ireland, to undergo an examination, the standard of which is beyond the capacity of the majority of medical students, or which is inconsistent with the method of education pursued at the medical schools. If we wish to improve the general standard of medical education without increasing an evil which is already inflicting a serious injury upon the public, we must begin with the schools, and make the system pursued there a sort of foundation on which the Conjoint Board or State examiners can work, and, further, the ordeal imposed by them upon the candidate, must not be such as would prevent the public having at its service a sufficient staff of duly qualified medical practitioners.

There is, indeed, every prospect that the future of medical education and medical examination will be a bright one. The establishment of a uniform system of examination throughout the United Kingdom will foster, and be fostered, by the adoption at the schools, of a more comprehensive and more practical method of teaching; the general standard of medical education will be improved; and the profession will hereafter enjoy the confidence and respect of the public more generally, and in a greater measure, than at any previous period of its history.

SIR MICHAEL HICKS BEACH.

We should do less than justice to the Ex-Chief Secretary for Ireland, whose energies have just been transferred to the Colonies, if we permitted his connexion with Ireland to cease without expressing our conviction that his departure from Dublin Castle will involve a serious loss to Ireland, and we hope we shall be excused departing—for this once—from our rule of excluding politics from our pages in order that we may point a moral with a reference to Sir Michael Hicks Beach. When he was first named in Dublin as the minister placed in charge of Irish affairs, everybody asked: Who is he? and the feeling was general that Ireland had been in this instance, as in many others, made use of to dispose of a partisan who could not be refused office, and who had not sufficient genius for any other ministerial position. This impression, Sir Michael Hicks Beach, before three months elapsed, completely removed, and he now carries back with him to England the respect which Irishmen are always ready to accord to a man of talent and firm principle. Sir Michael is not a popular man in the ordinary sense of the word; his ministerial attitude presented a happy contrast to that of some of his predecessors, whose policy was to be cap-in-hand to all useful people, no matter what they came to ask for, and to turn

a deaf ear to suitors who had few votes to give and little influence to exert. The late Chief Secretary made it his business to learn his business. When he met a deputation he was generally found to know rather more of what they had come to say than they knew themselves, and he was as pliant to grant a just request as he was inexorable in resisting a job or an impracticable scheme. He was never over-lavish with his favours to the doctors, but he always evinced a readiness to hear and give attention to their representations, and to grant, if permitted by the higher powers, such of their requests as seemed directed towards the public benefit. His greatest quality as a Chief Secretary was his anxiety to see the right man in the right place, and, while labouring under the supreme necessity of keeping the supporters of his Government in humour, he always strained a point to select a man who had some real qualification for office. From him the nameless and brainless place-hunter, who, heretofore, had had ready access to the Castle, *via* the back-stairs, met with little consideration. Let us trust Sir Michael Beach's successor will emulate his industry and attention to public affairs, even if he cannot compare with him in talents, and let us gratify ourselves with the hope that his Secretariate may be the starting point of a new policy of Irish Government patronage. The minister who shows himself strong enough to disregard the importunities of the busy-bodies of his own party, and to appoint the best obtainable men to public offices, whether they be Tory, Home Ruler, Radical, Orange, or Ultramontane, that minister will be Regenerator of Ireland. Hitherto, we state it with sorrow, not less with emphasis—no job has proved too hot or too heavy for Irish Governments so long as it satisfied the nameless hangers-on of their party, and the administration of Ireland has been in the matter of patronage nothing better than an alternate series of politico-religious jobs, in the excitement of which the special qualifications of candidates were barely considered. Is it surprising that the evil example of "the Castle" in this matter infected all public bodies, until within the last few years it has come to be an almost unexceptional rule that—from a Chief Justice to a Relieving Officer—from a Lord Mayor to a Dispensary Doctor—capacity, intelligence, or industry were habitually ignored in favour of politico-religious partisanship? Is it surprising, therefore, that young men do not—in Ireland—set themselves to climb the ladder of success by the force of their own energies and industry, when they see, from day to day, the discouraging spectacle of men as industrious and earnest as themselves set aside to make way for the relative of some influential partisan—the professor of some dominant religion—or for some impecunious and undistinguished jackal of the party in power?

Notes on Current Topics.

Cretaceous Degeneration of Arteries.

In a recent communication to one of the Parisian medical societies, Professor Gubler observes that the cretaceous change in the condition of the arteries which attacks the various classes of society in strangely opposite ways, affords a great contrast for study between the rich and the poor, the inhabitants of towns and the rural population. At the top of the social scale the arteries may retain their suppleness until the approach of confirmed old age, while in the lower classes the indurations manifest a remarkable precocity, so that arterial atheroma is met with in the hospitals in men of forty, thirty, or even twenty years of age. Doubtless, the abuse of alcohol is one of its powerful causes; but we must avoid attributing to it a too exaggerated operation. For while in the upper classes alcoholism is not so very rare, and yet it does not give rise necessarily to this degeneration, so in certain patients in the hospitals it is impossible to attribute the atheromata observed in them to abuse of alcohol. But the different diet made use of by the poor and the rich, the inhabitants of the country and of towns, may explain the facts observed. Thus, while one class obtains its nutriment from the flesh of animals and from vegetables abounding in nitrogen, in the poorer classes, bread, potatoes, cabbages, and herbaceous vegetables form the base of their alimentation. Flesh and albuminoid substances contain very small portions of mineral principles, while a purely vegetable diet contains a considerable proportion of the earthy phosphates and carbonates. The facility of cretaceous incrustation prevails in an inverse proportion to the vitality of tissues, so that the middle coat of arteries, but little irrigated with blood and of low vitality, is especially liable to undergo this atheromatous degeneration. If, then, this has its chief origin in earthy matters furnished by the herbaceous regimen, concurrently with potable waters loaded with earthy salts, the disease should be more precocious and more severe in calcareous regions like the Orléannois—a fact confirmed by M. Leblanc; while it should be rarer, or even absent, in siliceous, granitic, and volcanic regions, like Puy, where M. Vibert has shown it is a rarity. In monasteries, where the monks are confined to vegetable diet, the arteries are found greatly indurated at the early age of thirty-two.

The Galway Workhouse Clinical Instruction.

We noted recently, that the Board of Guardians had consented to admit students to the workhouse for the purpose of clinical teaching in connection with the Queen's College, Galway. Such teaching had been carried on for many years by the late Professor Cleland, but it was considered necessary to make new rules as soon as the instruction passed into other hands. The rules are before us, and some of them are so ridiculous as arrangements for hospital instruction, that they seem worth quoting:—

1st. That no student shall be admitted to or allowed to remain in the hospital or workhouse unless accompanied by the medical officer of the workhouse.

2nd. That the medical officer shall be responsible for the conduct of the students while in the workhouse, and shall report any irregularity to the board of guardians, and forthwith direct the porter not to admit the offending students again to the workhouse until the board have made an order to that effect.

3rd. That the medical officer shall accompany the students on their entrance to and exit from the workhouse.

4th. That under no circumstances shall any student be admitted to the workhouse before 10 o'clock, a.m., or after 4 p.m.

5th. That the names of the students attending on such occasion shall be entered by them on a book, to be kept by the porter for that purpose.

6th. That no student shall communicate with or interrogate any patient in hospital, except in the hearing of the medical officer.

7th. That no student shall, under any circumstances, interfere with the medical treatment of the patients—the object of the admission of students being merely their instruction.

The above rules were laid before the board of guardians, at their meeting of 18th January, 1878, and approved, with the following amendment :—

"That the hour for attendance of medical students shall be from 10 to 11 o'clock, a.m., on two days in each week."

The above rules have been printed recently by the board of guardians, and a copy is furnished to each student receiving clinical instruction from the medical officers of the workhouse hospital.

To comply with these regulations, the medical officer must attend outside the gate at 10 o'clock in the morning, to await the assembly of the students. Those who are not punctual, may stay outside. On entering the hall, the whole class must write themselves into the porter's book. They will then march through the wards in dumb show, not being permitted to stay a moment after the doctor to ask a question of the patient, listen for a chest sound, or examine a case, nor to dress a stump, adjust a splint, or "under any circumstances, interfere with the medical treatment of the patients." On the stroke of 11 o'clock, the medical officer must accompany them to the outside of the gate, and this proceeding repeated twice a week will constitute the clinical teaching of the Galway workhouse. We presume these rules are intended for show, and not for obeyance, otherwise we hardly understand how any physician can undertake to instruct a class under such circumstances.

On Heredity in Alcoholism.

In the *London Medical Record* for January, Dr. Charles Aldridge gives an interesting account of Taquet's observations on this subject. M. Taquet would place the abuse of spirits in the first line of causes which tend to depopulation. As Lancereaux has said, alcoholism is not only a disease of the individual, but is a family disease, and projects its evil influence upon the race. One sees it follows the individual in his offspring, his family receiving from him a fatal heritage in debility, deafness, a crowd of nervous disorders, moral imbecility, idiocy, mental alienation, and weaker instincts. The Indians of America have disappeared before the destructive powers of alcohol, when fire and sword failed to vanquish them. Daredin tells us that the families of drunkards become extinct in the fourth generation, after having descended through the scale of physical and intellectual degeneration. A remarkable case, cited by Taquet, in which most of the children of a drunkard showed serious manifestations of hereditary alcoholism, presented two important considerations :—1. That sexual desires show themselves early in children of drunkards, and are associated with an absence of moral sense; 2. That phthisis, when not hereditary, is capable of being produced by spirituous excesses. Magnus, Huss and Launay have supported this thesis by numerous examples. Again, other things being equal, the hereditary transmission will be more surely by the mother than by the father. The children of female drunkards are often idiots, imbeciles, insane, or epileptic. Of all the manifestations of alcoholic heredity, epilepsy is believed to be the most common. Of 95 epileptics examined by M. A. Voisin, 12 had ancestors who died from alcoholic excess. Marcet reports of a drunkard who had 16 children, that five were dead and the remainder epileptic.

Temperance in Elementary Schools.

A meeting to advocate the introduction of temperance teaching into the ordinary curriculum of public elementary schools will be held this day in Exeter Hall. The Lord Bishop of Exeter will preside, and the Dean of Bangor, Sir Charles Reed, Dr. Richardson, and several other influential gentlemen will take part in the proceedings. The object of the meeting is undoubtedly a good one, as, in most instances, there is more hope of improving the morality of the working classes by inculcating wholesome precepts in the minds of their children than if those who have long given way to habits of intemperance were the only persons dealt with. At the same time, it must be remembered that, in a matter of this kind, the rising generation are more influenced by example and by home influence than by all the moral teaching that can be provided for them in schools. As a rule, we do not find that the religious education of young children has very much influence upon their conduct in after years, and we are afraid that all the lectures or lessons on the evil results of intemperance will be forgotten by the time they are exposed to the temptations by which most of them are surrounded. It may even appear that the familiarity with the subject which such teaching will naturally involve may put into their young minds ideas and inclinations which otherwise they would never have entertained. The promoters of this movement, therefore, must not be too sanguine as to the beneficial results of temperance teaching. They can rest satisfied that the principle of the proposed scheme is a good one, and hope that more good than harm will come of it.

Headache in Renal Disease.

In the current number of the *Glasgow Medical Journal*, Prof. Gairdner draws attention to the importance of headache as a symptom of renal disease, and cites two interesting cases in support of his observation. He remarks that this symptom has not been so commonly or so strongly insisted upon by authors, at least, in the subacute types of renal disease, and in the uræmia arising from it. Dr. Gemmell, in his large experience of scarlatina at the Fever Hospital, became quite familiar with headache as a symptom of the renal affection following that disease. Bartels, in Ziemssen's "Cyclopædia," alludes to "frequent and severe attacks of headache sometimes occurring under the forms of excessively severe hemicrania of remarkably long duration," as formerly one of the earliest evidences in some cases of renal cirrhosis ; and a somewhat similar remark is made by Dr. Murchison, who also draws attention to the neuralgic character of the pain, and infers—as does the German author—that attacks of *migraine*, occurring after middle life, ought always to lead to careful

scrutiny of the state of the urine. Dr. Gairdner likewise remarks on the value of benzoic acid and of purgatives in the treatment of these cases. With regard to the former, which has been much employed in Germany against uræmic attacks during pregnancy and after delivery, Dr. Gairdner found that in doses of 5 grains three times a day, it had a prompt and excellent effect upon a patient who was suffering from this complaint, accompanied by muscular spasms, faintness, extreme weakness, and in whom an attack of general convulsions appeared to be imminent. She had all the appearance of having been "rescued from a nearly hopeless state of impending death." She was ultimately discharged quite well, without either albumen or tuberculosis being perceptible in the urine, and she continued to enjoy better health and strength than she had for years previous to the dropsical attack.

Small-pox and the Public Health in Dublin.

VARIOLA is, we regret to say, very prevalent in Dublin. In the week ending Jan. 26th, four cases died, none of whom had been vaccinated, and three of whom suffered from the confluent type. Within the year 1877, thirty-eight deaths were registered within Dublin; thirty-three from the city, two from the suburbs, and three from other districts.

The Sanitary Association, at their last meeting, reported that since the 1st of February, 16 cases had been admitted into Cork-street Fever Hospital, and there are altogether 27 cases there. The *Daily Express* says, that much of the evil is due to the obstinate neglect of parents in the poorer classes to have their children vaccinated. It does not appear, however, that the provisions of the law in this respect are carried out with sufficient strictness, and the effect is that the people in the humble ranks of life are allowed with impunity to indulge their indolence or prejudice, and keep their children unvaccinated. Seven of the cases brought into Cork Street hospital were of this class. The public are apt to forget the ravages made by such visitations when the danger passes away, and it is well to remind them that in the epidemic of 1871 and 1872, no fewer than 1,647 lives were lost by it, and the cost to the ratepayers of the city was £30,000.

The death-rate of the city, which for a couple of weeks had fallen to a moderately high level, has again risen, and, for the week ending Feb. 2, stood at 32·6 per 1,000, London and Glasgow being only a fraction over 24 per 1,000. This excessive mortality had no reference to the prevalence of small-pox, for there was no death from that cause that week. We do not hear that the Public Health Committee of the Corporation is making any effort whatever to save the lives of the citizens.

Treatment of After-Pains.

AT the last meeting of the Obstetrical Society of Edinburgh Dr. Allan Jamieson read a paper on the systematic prevention of after-pains, in which he advocated the use of ergot in every case of labour. Professor Simpson thought the subject an important one, and wished he could feel sure that this line of treatment would always succeed. Dr. Gordon found chloral of most service in such cases. He, and two or three other members, saw no need of injecting ergotine, as the old method of giving the remedy was quite satisfactory. The treatment of after-pains has often been a subject of discussion, and it is evident from the remarks made at the above meeting that the question is not settled yet. It may even be doubted whether the cause of these pains is exactly understood. Sir Charles Locock used to make a point of clearing the uterus of all clots directly after the placenta had come away, as he was convinced that this plan ensured uterine contractions and prevented the occurrence of after-pains. At all events, narcotics should not be resorted to except in cases of great severity, when a full dose of Dover's powder will generally give speedy relief. Ergot is perhaps most useful in the case of women who have had several children.

The Throat Hospital, Golden Square.

OUR readers will remember that during the past year this hospital has been under a cloud owing to alleged mismanagement. In July last, in consequence of certain grave charges and the resignation of a portion of the staff and officials, H.R.H. the Prince of Wales, as patron of the Institution, ordered an inquiry to be held, the result of which was, the withdrawal of Royal patronage, the resignation of the Marquis of Bute as president, and the withholding of the usual grant by the Hospital Sunday Fund. Of course, no Institution dependent upon voluntary support, could long exist under the suspicions to which its management would necessarily be subject on account of the unfortunate circumstances referred to. A number of the influential subscribers have, therefore, requested the secretary to convene a general meeting, and the following notice has been forwarded to us.

"We, the undersigned subscribers to the Hospital for Diseases of the Throat, 32 Golden Square, London, W. in accordance with bye law 38, do hereby request you to convene a special general meeting of subscribers. The objects for which we require such meeting to be held are as follows:—1. 'To receive a letter from Sir Dighton Probyn, enclosing, by permission of his Royal Highness the Prince of Wales, the report of the committee of inquiry, held on the 14th of July last, at the request of his Royal Highness, into the alleged mismanagement of the medical department of the Hospital. 2. To receive the report of the committee of inquiry above-mentioned, which it appears has resulted in the withdrawal of the patronage of their Royal Highnesses the Prince and Princess of Wales, and in the resignation of the Marquis of Bute, the President of the Institution. 3. To take such steps as may be necessary to reorganise the hospital, so as to justify the renewal, if possible, of their Royal Highnesses' countenance and support.'"

Signed by:—The Marquis of HAMILTON, M.P (Vice-President), the Earl of PEMBROKE, (Vice-President), the Earl of ILCHESTER (Vice-President), Earl Cowper (President 1874-5), the Earl of ROSEBERY, Lieut.-Col. Lord EUSTACE CECIL, M.P., the Hon. WILBRAHAM EGERTON, M.P., SIR CHARLES LEGARD, Bart., M.P., Sir LOUIS MALLET, C.B., Mr. A. BOWRING, Mr. SIDNEY HARGROVE, Captain HUGHES-HALLETT (Vice-President), Mr. E. N. LEVY, Mr. JOHN W. MALCOLM, M.P., Mr. H. B. MILDMAY, Colonel W. PINNY (Vice-President), Mr. F. R. WEGG-PROSSER, and others.

Royal Free Hospital.

On Thursday evening Mr. James Hopgood presided at the 50th annual meeting of this charity, held at the hospital, Gray's-Inn Road. The institution, which originated in a "small beginning," in a house in Greville Street, Hatton Garden, has now developed into one of the most important charitable institutions of London. A new wing, containing 50 additional beds, has been erected from the designs of Mr. William Harvey. In addition to this the committee have resolved upon erecting block No. 2 of the new buildings, which will consist of nurse's room, isolated wards, and board room. During the year, the hospital has opened its doors to lady medical students, an arrangement having been made that £400 per annum be paid to the medical staff for clinical instruction, and an additional £315 annual subscription to the Hospital Funds by the London School of Medicine for Women. The number of patients received into the in-patient department during the year was 1,369. As regards out-patients the number has decreased this year, owing to the building operations which have been going on during the year, and was only 5,099. The newly erected wing contains, besides three large wards, affording accommodation for 50 in-patients, an entirely new out-patient department. Legacies to the amount of £14,037 were announced in the report, and from Hospital Sunday Fund £487 was received, while Hospital Saturday Fund contributed £134. In addition to these amounts various sums are acknowledged from several city companies, and smaller contributions.

Our Poor Profession.

Having the painful duty frequently to record cases illustrative of the poverty of our profession, it gives us pleasure to present the opposite side. Two or three weeks since our obituary contained the death of Dr. James Blundell, of No. 80 Piccadilly, London, which took place on January 15th, at the ripe age of 87. Deceased's will has just been proven by George Augustus Frederick Wilks, M.D., the nephew, and Samuel Frederick Noyes, the surviving executors, the personal estate being sworn under £350,000, besides considerable freehold and household property. The testator leaves to his sister, Miss Mary Blundell, an annuity of £800, and all his furniture, plate, pictures, household effects, horses and carriages; to his half-sister, Miss Ann Blundell, an annuity of £250; to his nephew Bezer Blundell, £14,000 consols; to his nephew Dr. Wilks all his freehold, copyhold, and leasehold estates and £35,000 reduced bank annuities; to the London Hospital, £500; to St. Mary's Hospital, Paddington, £250; and there are other legacies and annuities to relatives, friends, and servants.

The New Museum of Science and Art in Dublin.

Dr. Steele, Secretary of the Royal Dublin Society, and of the Branch Medical Council for Ireland, has received a letter announcing that the Government offer him the appointment of Director of the Museum of Science and Art in Dublin. Lieutenant-Colonel Donnelly, in communicating the offer to Dr. Steele, writes that it is made in recognition of his long and valuable services in connection with the department as Secretary of the Royal Dublin Society, and from the belief that the experience Dr. Steele has gained in the office will be of the utmost value to them in the establishment of the new museum. The salary attached to the new office will be £500, with an annual increment of £25 until it reaches £600, with a residence but the maximum salary of £600 will be paid to Dr. Steele from the 1st of April next. A sum of £160 a year will be allowed for a residence until one is provided.

Spectacles and Beards in the French Army.

A Paris correspondent says in a recent letter: Among the lessons learned by the French in the late Prussian war is the fact that, with the aid of spectacles, short-sighted soldiers can fight as well as those whose sight is not affected. On the representation of Dr. Perrin, one of the professors of Val-de-Grâce, a ministerial circular authorises the rank and file, in common with officers, to wear spectacles whenever considered necessary. The consequence is, that myopic subjects, who used formerly to be rejected, are now enlisted in the French army.

Another ministerial circular, ordering officers and soldiers to wear the moustache and beard, has lately appeared. The latter is to be in the form of a *mouche*, consisting of only a small tuft under the lower lip—the style of the royalists. This was superseded, under the Empire, by a fuller beard, called the "imperial;" but those in the colonies have the option, or not, of wearing the full beard; all officers and soldiers to have their hair cut quite close.

The Genesis of Red Corpuscles.

M. G. Pouchet has (says the *London Medical Record*) brought a communication on this subject before the Société de Biologie. His conclusions were based on an examination of the blood and the intimate structure of the spleen in the Selachian fishes. Thus, in *Scillium catula*, the blood invariably contains corpuscular elements which cannot be distinguished from those which make up the splenic parenchyma. These elements are smaller than ordinary leucocytes; they exhibit a pearly lustre by transmitted light; their surface presents smooth protrusions of sarcodic matter; and they contain a voluminous nucleus which turns slightly brown under the influence of osmic acid. These elements pass through a series of intermediate stages into fully-formed red corpuscles; they increase in size, lose their sarcodic properties to assume a regular figure, their nuclei shrink, and hæmoglobin appears in their interior.

German Medical Students.

The Official Almanack informs us that the number of medical students entered at the various German schools during the past year was 6,116. Vienna still stands at the head of the list with 755 students, while Berlin counts only 281, coming sixth on the list, after Prague. Strasburg has 222 students; Heidelberg 84; while Rostock, the lowest on the list, has only 34.

According to a telegram from Shanghai, dated Feb 3, the Asylum for Women and Children at Tientsin had been destroyed by fire. More than two thousand persons are stated to have perished in the flames.

The Milk of an Esquimaux Woman.

THERE is, says *La Presse Médicale*, among the Esquimaux now to be seen at the Zoological Gardens, Brussels, a young mother, who suckles two infants. Dr. Condereau, of Paris, has analysed the milk of this woman, and compared it with that furnished by Europeans. According to his researches, the Esquimaux's milk contains a less proportion of salts, but it is rich in sugar, and esp ecially in fat. This abundance of hydro-carbons agrees with the habitual regimen of the Esquimaux, who resist the cold to which they are exposed by consuming a large quantity of fatty food.

Nutrition of Amœbæ.

IN a lecture on the protoplasmic theory of life, delivered by Professor Garrod at the Royal Institution, the lecturer propounded a new theory respecting the nutrition of amœba, foraminefera, and amœbiform bodies generally. The protrusion of the pseudopodia has hitherto been regarded as a motion in search of food, but Professor Garrod considers it to be in reality a temporary growth. When the supply of nutriment ceases, growth ceases, and the death of the part follows. The salts of lime which form shells and the bones of the higher animals, are, according to this view, all precipitated through chemical action around the amœbiform bodies. The full report of this lecture will be looked for with some interest.

Opium Eating in the United States.

THE total amount of opium imported into the United States for 1877 was 2,589,924,383 grains. Deducting one-fifth for medical uses, there remain for opium eaters 6,125,383 grains daily. If thirty grains are taken as a daily dose, there are in the United States over 200,000 men who eat opium.

Fasting.

A PROVINCIAL paper says that another Welsh fasting girl has come to light. Her name is Morgan. She is about fifteen years of age, and is said not to have eaten nor drunk anything since the 30th of October last.

ANOTHER death occurred last week from the administration of chloroform. The deceased was a sailor named Michael Cain, who met with an accident, and was taken to the Northern Hospital, Liverpool, where it was found that he was in danger of losing his sight. An operation was decided upon, and the surgeons administered chloroform; but in a few minutes the patient died from failure of the heart's action. A coroner's inquest was held on Saturday last, when the jury returned a verdict accordingly, and exonerated the surgeons from blame.

SMALL-POX caused 38 deaths in London last week, of which 26 occurred in the special hospitals, and 12 in private dwellings. Judged by the number of cases under hospital treatment, the epidemic is decidedly on the increase. The number of small-pox patients in the hospitals in October last, was 137, since which it has steadily increased to 542 at end of last week, rather an alarming state of things.

Gastrotomy.

AT a recent meeting of the Academy of Medicine in Paris, Dr. Cagin, of Bologne, read a paper on a case of gastrotomy performed in consequence of an intestinal occlusion. The operation, he observed, is applicable to certain cases of internal hernia from bands, or twisting, those which occur suddenly, by complication. It is not necessary to know exactly the seat of the evil in order to intervene. All delay in operating diminishes the chance of success. If there be any doubt about the seat of the strangulation, the incision should be performed in the median line to an extent proportionate to the difficulty of finding the seat of the malady. Parise's method which simplifies the manipulatory measures, should be used; and there should be extreme care as to cleanliness, and Lister's antiseptic method should be used.

The Abuse of Tobacco Prizes.

THE *Gazette Medicale* says that the Paris Société contre l'Abus de Tabac has received no less than 108 manuscript essays for its prizes of 1877, for the best essays on the abuse of tobacco. Of these 14 come from England 1 from Belgium, and 1 from Germany. The authors, most of whom are medical men or schoolmasters, are informed by the Society that several months must elapse before the committee can have finished its examination of such a number of essays.

Cremation.

AN opportunity will be afforded to-day at the Society of Arts for the public to acquaint itself with the method of cremation now practised on the Continent. Mr. W. Eassie is to lecture on the subject, and he will, without doubt, exhaust it.

THE President and Fellows of the King and Queen's College of Physicians in Ireland give notice that Dr. Aquilla Smith has been continued in his office as the King's Professor of Materia Medica and Pharmacy in the School of Physic in Ireland, for a further period of seven years from the 12th of May next, in conformity with Section 24 of the School of Physic Act.

THE mortality last week in the four principal cities of the United Kingdom, was at the rate of 25 per 1,000 of the population in London and Glasgow, 27 in Edinburgh, and 33 in Dublin. Of the large towns in the second category, Portsmouth was lowest in the list with 16, and Plymouth highest with 35. Manchester and Norwich being next with 33 per 1,000.

ST. PETERSBURG shows again the highest rate of mortality of any city in the world, whose returns are sent weekly to the Registrar General. Typhoid and relapsing fevers are excessively prevalent, the gross deaths from all causes amounting to the extraordinary total of 51 per 1,000 of the population.

THE appointment of Physician in Ordinary to Her Majesty's Household, vacant by the death of Dr. Francis Hawkins, has been conferred upon Dr. Russell Reynolds.

In addition to the terrible sufferings of cold and hunger, which the refugees in different parts of European Turkey are suffering, small-pox and typhus fever have broken out in their midst, with fearful virulence.

A TELEGRAM from Mysore states that the census shows that 25 per cent., or a million and a quarter, died during the famine, and that 35 per cent. of the poor classes have disappeared.

THE Registrar General reports that whooping-cough is fatally epidemic in Plymouth and Wolverhampton.

Correspondence.

A CAUSE OF DEATH DURING TRACHEOTOMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of February 6th there is a communication by Dr. Norman Chevers, in which he mentions several cases of diphtheria in which tracheotomy was followed by immediate death. I may, perhaps, be able to throw some light upon the cause of this disastrous mishap by relating a case which occurred in my practice some years ago.

In the early part of 1874 I was asked by a colleague to see a patient with him who was suffering from œdema of the lung and excessive inspiratory dyspnœa. On examination, I found that the larynx and the trachea, as far as I could see, were quite œdematous. My prognosis was very unfavourable, and it was only after repeated urging that I determined to tracheotomise, in order to afford the sufferer some, if only temporary, relief. On the following day, the patient being slightly under the influence of chloroform, I proceeded to operate. The trachea was readily exposed, respiration going on quietly. As soon as I plunged my knife into the trachea violent dyspnœa set in, which, increasing as I cut the tracheal rings, I thought might be due to the anæsthetic; the chloroform was suspended, and, dividing five of the cartilages as speedily as possible, I introduced a large, hard rubber canula. Speedily as this was done, it proved of no avail, for the patient was dead. With the permission of the family, a *post-mortem* was made the next day, and the larynx, with its adnexæ, was removed, in order to allow of a careful examination. It was found that the incision had divided five of the rings of the windpipe, but the knife, instead of dividing the lining mucous membrane had separated it from the anterior and lateral walls of the trachea, and the more I cut the more I pushed the membrane before me, and thus cut off the supply of air; the introduction of the tube merely capped the climax.

My distress was extreme, and, in searching for the records of similar cases, I chanced to alight upon a number of the "Bulletin" of the Royal and Imperial Medical Society of Vienna, of the year 1851 (I cannot be exact, for the files are not at hand). In this number there is a paper by Prof. V. Pitha, of the Military Academy of Vienna, on "*Decoulement de la Membrane Muceuse de Trachée*," *i.e.*, loosening of the mucous membrane of the trachea. I there found that a similar accident as that just mentioned had occurred to the distinguished operator, and that Dupuytren, the great French surgeon, had also had two like mishaps occur in his practice. Von Pitha says that the loosening of the mucous membrane is due to an œdematous infiltration of the sub-mucous areolar tissue, which admits of the detachment of the lining membrane.

Taught by experience, since that time I never fail, in tracheotomising, to secure a firm hold upon the mucous membrane by plunging a tenaculum into one of the upper intercartilaginous membranes as soon as the trachea is exposed. By so doing the windpipe is steadied, and the division of the cartilages and the lining membrane can be proceeded with at leisure.

Yours very truly,

RICHARD C. BRANDEIS, M.D.

20 Bentinck Street, Manchester Square, W.
February 11th, 1878.

THE CARMICHAEL PRIZES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—What does the Council of the Royal College of Surgons in Ireland intend doing with reference to the Carmichael Essay? I make the inquiry with a view to legal action, as I, for one, am quite determined that the decision of the Master of the Rolls shall not be allowed to remain a dead letter. I would be glad to hear from your other correspondent. He need not fear ultimate punishment from the College Authorities for the favour, and the Carmichaels will effectually provide for the punishment of partiality in the award.

MEDICUS.

PROFESSIONAL ADVERTISEMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above heading, in your last issue, you alluded to an article which appeared in the *Dublin Evening Mail* recently, by which your sense of personal and professional decorum was outraged, and you cast the following imputation on me:—

"That I had caused a newspaper puff (having my name prominently introduced) to be written, and supplied the reporter with the pabulum thereof."

I do not know whether you have made this assertion from information furnished you by others, or from an assumption of your own. In either case—if the former, the statements told you were untrue; if the latter, you yourself were incorrect—I distinctly deny having ever, directly or indirectly, availed myself of the public press as a means of personal advertisement.

Your obedient servant,

R. L. SWAN.

[We have not made any charge against Dr. Swan in the terms attributed to us. Our complaint was in reference to a "breach of professional decorum, all the more open to censure because it is perpetrated under the apparent cognisance of a surgeon or surgeons . . . . one of whose names is prominently set forth in this newspaper puff," &c., &c., and we distinctly expressed our opinion that it would be consistent with his own self-respect that the surgeon in charge of the institution "should repudiate a proceeding with which his name is so directly connected." We are gratified to be allowed to publish Dr. Swan's assurance that he never, "directly or indirectly, availed" himself "of the public press as a means of personal advertisement." We shall be still better pleased if he allows us to say that he emphatically disapproves of the surgical successes of any surgeon being recorded in the public papers—that he was not cognisant of such a record in the past, and will not countenance it in the future.—ED. M. P. & C.]

The Profession at the Levée.—By command of the Queen, a Levée was held on Saturday last at St. James's Palace, by H.R.H. the Prince of Wales, on behalf of Her Majesty. The following members of the profession had the honour of presentation, all belonging to the Army Medical Service :—Deputy Inspector-General John Elliott, M.D., on promotion, by the Director-General, Army Medical Service ; Inspector-General D. Lloyd Morgan, C.B., M.D., on promotion, by the Director-General, Army Medical Service ; Surgeon G. B. Stuart, M.B., Grenadier Guards, on appointment, by H.R.H. the Duke of Cambridge.

The following also attended the Levée :—Sir Joseph Fayrer, M.D., F.R.S., Drs. Wilson Fox, T. King, Chambers, Brodie, Lewell, George Bridwood, Reginald Read, William Hickman, Ivey, and Rae.

NOTICES TO CORRESPONDENTS.

An Undergraduate is thanked for his letter in confirmation of our views ; we cannot, however, re-open the discussion as little can be advanced on either side which has not been already said.

A Sanitary Laundry.—We have been asked to direct the attention of our readers to an undertaking just started under the title of "The Metropolitan Sanitary Laundry Association." It is in the form of an ordinary limited liability company, except in those objectionable features—promotion money, founders' shares, &c., which are not here recognised. The directors are all medical men, consisting of Dr. W. H. Haden, Dr. Arthur Leared, and Dr. Dudfield, assisted by a ladies' committee of management for the indoor department. The objects of the Association are sufficiently explained in its title, and beyond the advantages sought to be obtained for the public, the Company is also expected to pay a good commercial dividend to shareholders. In order to effectually prevent contagion, and to ensure perfect immunity from those ills to which the householder is liable when sending linen from home, the Association, through its medical directors, guarantee that "the employés of the Association will be engaged on certain conditions, having special reference to the health and sanitary condition of their respective households, which will be constantly and carefully inspected by the Company's sanitary officer. Where illness of an infectious or contagious character exists in the household of any one using the Association's Laundries, notice of such illness shall be sent to the manager—the non-compliance with this rule will entail forfeiture of all shares and privileges. All linen will be disinfected in specially-constructed chambers."

The Medical Alliance Association.—In giving the draft of the Bill for the Amendment of the Medical Act in our last we omitted to state that it is drawn up by the Medical Alliance Association, and is down for the second reading on Feb. 20th. The Association, we may add, has done much good work in prosecuting unlicensed practitioners and prescribing chemists. Its action is somewhat impeded for want of adequate support. Dr. Carpenter, of 130 Stockwell Road, S.W., is the Hon. Sec., and will be glad to enrol additional members on payment of the annual subscription of 10s. 6d.

Dr. Langhet, Rheims.—We cannot add to our already heavy exchange list. Our publisher has been directed to send you an occasional copy.

Mr. B. L. S.—You are wrong altogether in your law ; the authorities have full power to act as they have done, and we can only counsel you to submit.

Mr. Worth's letter, with editorial reply, will appear in our next.

Royal College of Surgeons of London.—Wednesday, Friday, and Monday, Feb. 13, 15, and 18, at 4 p.m., Prof. Parker will lecture "On the Morphology of the Batrachia."

Hunterian Society.—Wednesday, Feb. 13, at 7½ p.m., Annual Meeting for Election of Officers. At 8 p.m., Annual Oration by Mr. P. L. Burchell.

Dr. C. B. Fox, Chelmsford.—The numbers in 1860, containing the series of articles mentioned, are out of print. You will doubtless be able to refer to them at the British Museum, or at one of the medical colleges.

Fair Play, on "Medical Women," too late for our present issue.

More Curiosities of Medical Literature.—We find the following in a local paper :—"A Distinguished Waterford Man."—Among st those who distinguished themselves at the examination held last week at the King and Queen's College of Physicians, Dublin, we observed the name of Mr, —— ——, L.R.C.S.I, L.M., son of Mr, —— ——. At the examination we allude to, Mr, —— obtained his diploma as physician, standing, at the end of the examination, many points higher than his fellow-students, whilst the following day, in the midwifery examination, he was congratulated by the professors—one of the greatest compliments any student has received. We understand Dr. —— intends practising in the city, and taking into account his distinguished collegiate career, we have no doubt he will fall into a practice not only lucrative to himself but to the advantage of the citizens generally. The "distinguished collegiate career" of Dr. —— does not seem to have done much to cultivate his sense of social or professional propriety.

Royal Institution.—Thursday, Feb. 14, at 3 p.m., Prof. Dewar, "On the Chemistry of the Organic World." Friday, Feb. 15, at 9 p.m., Weekly Meeting. At 9 p.m., Dr. P. L. Sclater, "Zoological Distribution and some of its Difficulties." Saturday, Feb. 16, at 3 p.m., Mr. Bosworth Smith, "On Carthage and the Carthaginians."

Communications, Enclosures, &c., have been received from Dr. Wilson Fox, London. Mr. H. Cripps Lawrence, London. Dr. Langhet, Rheims, France. Dr. Beverley Johnson, New York. Dr. Broadbent, London. Dr. Wheeler, Dublin. Dr. Fort, Paris. Dr. Swan, Dublin. Dr. Offenberg, Wickrath, Rhenish Prussia. Mr. Lloyd, Pontypridd. Dr. Norman Chevers, London Hospital. Dr. F. Agar, Ponder's End. Dr. Fano, Paris. Mr. Gilman, Norwich. Mr. Oliver, Manchester. Mr. Thornton, London. Mr. Douglas Hemming, Notting Hill. Dr. Handfield Jones, London. Dr. Dolan, Halifax. Mr. Hall, Lincoln. Mr. Rundle, Crediton. Dr. Gillespie, St. Thomas's Hospital. Dr. W. H. Haden, London. Mr. Caddy, London. Mr. Burke, Clifden. Dr. Haddon, Manchester. Dr. Squire, London. Mr. Wordsworth, London. Dr. Stretch Dowse, Hornsey. Mr. Felix Weiss, London. The Director-General Army Medical Department. Mr. Hills, Guy's Hospital. Dr. Carpenter, London. Mr. Gure, London. Mr. Rickards, Derby. Dr. Wilmot, Dublin. Mr. Worth, Nottingham. Dr. Loring, New York. Dr. Cooper, Notting Hill. Mr. Williams, Dublin. Mr. Bridges. Dr. McNaughton Jones, Cork. Mr. James, Belfast. Mr. Campbell, Dundee. Dr. Hamilton, Glasgow. The Director-General Indian Medical Department. Dr. Cornelius Fox, Chelmsford. Mr. F. C. Wells, Finsbury. Mr. Simson, Eltham. Dr. Meymott Tidy, Islington, &c., &c.

VACANCIES.

Altrincham Rural Sanitary Authority.—Medical Officer of Health. Salary, £800 per annum, to include all expenses. Applications to the Clerk of the Joint Committee, Union Offices, Kingsford, Cheshire.

Clifden Union.—Medical and Sanitary Officer for the Clifden Dispensary District. Salary, £90, exclusive of fees. Election, 13th inst. (See Advt.)

Downpatrick Union, Strangford Dispensary.—Medical Officer. Salary, £100. Election, Feb. 21.

Gort Union, Ardrahan Dispensary.—Medical Officer. Salary, £140. Election, March 14.

Hertford General Infirmary.—House Surgeon and Secretary. Salary, £100, with board and lodging. Applications to the Chairman of the Weekly Board, Hertford.

Hospital for Women, Soho square, W.—House Physician. Full particulars of the Secretary.

Killala Union, Killala Dispensary.—Medical Officer. Salary, £60. Election, March 2.

Liverpool Royal Infirmary, School of Medicine.—Lectureship on Botany. Full particulars of the Registrar.

Lincoln Lunatic Hospital.—Medical Superintendent. Salary, £150, with board, lodging, and washing. Applications to R. Hall, Esq., 38 Silver Street, Lincoln. (See Advt.)

Manchester Hospital for Sick Children at Pendlebury.—Medical Officer. Salary, £100, with board and residence. Applications to the Chairman of the Board. (See Advt.)

Surrey Dispensary.—Dispenser. Salary, £80, with partial board. Hours of attendance, from 9 a.m. to 6 p.m., daily. Full particulars of the Hon. Sec., 190 Tooley Street, S.E.

Westminster Hospital.—Aural Surgeon and an Assistant Surgeon, both Honorary. Election, Feb. 26. Candidates must attend a meeting of the Board on the 19th inst., with testimonials.

West Norfolk Hospital.—House Surgeon and Secretary. Salary, £100, with board, lodging, &c. Applications to the Chairman of the Weekly Board, Lynn, Norfolk.

APPOINTMENTS.

Atkins, R., M.D., M.Ch., Resident Medical Superintendent to the Waterford District Lunatic Asylum.

Bellamy, E., F.R.C.S., promoted to Surgeon to the Charing Cross Hospital.

Elsom, F. J., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Whitwell District of the Worksop Union, Notts.

Fox, Dr. C. B., Medical Officer of Health for Chelmsford, elected Fellow of the Chemical Society.

Paul, F. T., L.R.C.P.L., M.R.C.S.E., Pathologist at the Liverpool Royal Infirmary.

Reynolds, J. R., M.D., Physician to the Household in Ordinary to Her Majesty.

Deaths.

Armstrong.—On Jan. 29, at Manorhamilton, Christopher Armstrong, M.B., L.R.C.S.I., late of the 84th Regiment, aged 34 years.

Brown.—On Feb. 2, at Wooler, Northumberland, Joseph Brown, L.R.C.P. Ed., aged 66.

Cooper.—On Jan. 26, at Tombland, Norwich, Emanuel Cooper, L.S.A.L., aged 75.

Fry.—On Jan. 29, at Maidstone, Frederick Fry, F.R.C.S.E., aged 68.

Jones.—On Feb. 4, at Blackfriars Road, Frederick Charles Jones, M.D., aged 61.

Pelly.—On Jan. 30, at Eyrecourt, co. Galway, James Pelly, L.R.C.S.I.

Tayler.—On Feb. 2, at Trowbridge, Christopher Tayler, M.R.C.S.E., aged 62.

Wilson.—On Jan. 29, at Stretford Road, Manchester, Alexander Wilson, M.D., aged 57.

IRISH POOR-LAW INTELLIGENCE.

TRALEE GUARDIANS.

IMPORTANT TO DISPENSARY DOCTORS.

THE following communication, received from the Local Government Board, was read by the Clerk :—

Local Government Board,
Dublin, January 12, 1878.

SIR,—The Local Government Board for Ireland have observed in the minutes of proceedings of the Board of Guardians of Tralee Union on the 22nd ult., a notice to move that their sanction be requested to a proposal to deduct from the salary of Dr. Harrold, medical officer of the Brosna Dispensary District, the sum of £17 17s. surcharged by the auditor against certain guardians at the recent audit of the union accounts ; and the Board desires to state that they could not interfere in this matter in the manner in which the terms of this notice contemplates.

By order of the Board,
B. BANKS, Secretary.

To the Clerk, Tralee Union.

Mr. Kenny—I believe there is a notice of motion by Mr. Loughnane to be discussed to-day on the same matter?

Clerk—There is.

Mr. Loughnane—Dr. Harrold said he was suffering from a little nervousness, caused by family affliction, and he got a certificate from Dr. Hannafin to that effect, and sent it to his cousin, Mr. Roche, the secretary of our committee, who called a meeting, and gave him a month's leave of absence, and to advertise for a substitute. There was no substitute appointed at the time, and in the middle of that week a most frightful case turned up. There was no doctor to attend to it, and I came at once to Castleisland and met the secretary, and told him that the case was likely to turn out a bad one, and that it was better for us to do something. I accordingly got Dr. Nolan to attend the patient. Dr. Harrold was too nervous to attend a "red ticket" call, while one week during the leave of absence he earned £12. Dr. Nolan's bill was £17 17s., and he was paid it, but it appears the auditor surcharged the three gentlemen who signed the cheque—gentlemen who had no connection whatsoever with the district. What I propose now is, that this sum of £17 17s. be deducted by the Clerk out of Dr. Harrold's salary.

Mr. Herbert—I'd like to know who is to be the judge of whether a man is sick or not? What stronger proof could be given than the certificate of a medical man? We all know that Dr. Hannafin is a well-qualified medical practitioner, and I have heard people from Milltown say that he is regarded as a first-class medical man (hear, hear). My friend Mr. Loughnane turns round and says that Dr. Harrold attended private patients.

Mr. Murphy thought it right to say that Dr. Harrold filled the onerous duties of medical officer of that district for 27 years, and during the time he was always known to command the confidence of the people. He was a most eminent doctor, and most attentive to the wants of the poor. He hadn't heard a complaint against Dr. Harrold of any kind for the 16 years that he (Mr. Murphy) knew Brosna. He was aware that Dr. Harrold's mother-in-law, brother-in-law, and sister-in-law died, and he thought that after such afflictions in one family, there was little to be wondered at his getting a month to refresh himself—a very reasonable time. He would suggest that the whole matter be referred to the Local Government Board.

Clerk—There is a letter from the Local Government to-day which I read for you, stating they cannot interfere in the matter.

Mr. Murphy—Gentlemen, I hold in my hand a paper called the *Medical Press*——

Mr. Loughnane—I suppose you got that the night of the dinner (laughter). Ye had a dinner there this week (laughter).

Mr. Herbert—Hear Mr. Murphy (order).

Mr. Murphy—I hold in my hand a paper called the *Medical Press* of September 29, 1875, which contains an editorial note on certain proceedings in the Waterford Union. I'll read it for you, and I think it bears very strongly on this ease.

Mr. Kenny—What do we know about the *Medical Press*, Mr. Murphy?

Mr. Murphy—It is a case in point.

Chairman—Hear Mr. Murphy. Go on, please.

Mr. Murphy—I was calling your attention to this paragraph in the *Medical Press*. Here it is :—

"We really cannot understand why medical officers should put themselves under a compliment to their committees, or put their *locum tenens* in a delicate position as regards payment for temporary services rendered in case of the incapacity of the medical officer to discharge his duty. The regulations of the Local Government Board, which we have more than once republished for the information of Poor-law medical officers, indicated a simple course which the medical officer shall adopt in case he falls ill. He is to write to the secretary of his committee or the clerk of his union, in case he be a workhouse officer, stating simply that he is no longer able to continue work, and recommending a qualified medical man for appointment as his substitute. This done, he has nothing further to say to the matter. The committee or guardians have no power whatever to stop his pay, or make any deduction therefrom. They may or may not adopt his recommendation as to the choice of a *locum tenens*, and if any medical officer is foolish enough to accept the office without an understanding as to payment they may give him anything or nothing. He can name his own remuneration, and the sick officer has no more liability in that matter than any member of the committee."

Mr. Kenny—The Local Government Board is a better authority than the *Medical Press*.

Mr. Brick—I don't think it is in our power to stop this from Dr. Harrold.

Clerk—If you did, the first thing Dr. Harrold would do would be to bring a process against me for the amount.

Mr. M'Cowen—Did Dr. Harrold comply with the Act of Parliament when he got this leave of absence?

Mr. Murphy—He did, sir.

Mr. M'Cowen—I don't think he did.

Mr. Murphy—Oh, he did.

Mr. M'Cowen—Are you sure now?

Chairman—Didn't he desert his post?

Mr. Murphy—He got leave.

Mr. Kenny—I wish to know the opinion of our respected Inspector, Mr. Horsley, on this matter?

Mr. Horsley—Upon what point?

Mr. Kenny—Who is to pay for a substitute for Dr. Harrold?

Mr. Horsley—It is certainly not Dr. Harrold himself. It is quite clear you cannot stop this sum of £17 17s. from his salary either. It is the duty of the committee to appoint a substitute for a medical officer when unwell, and the services of a substitute having been so obtained, and the duties properly discharged, then, of course, it is the duty of the Board of Guardians to see that he would be paid, such sum to be levied off the electoral divisions comprising the district.

After some further discussion, the following resolution was adopted unanimously :—

"Resolved—That with reference to the surcharge of £17 17s. made by the auditor, and with reference to the letter of the Local Government Board of the 12th inst., we request them to ask the auditor not to press payment of the surcharge against the guardians named, inasmuch as the medical services were given by Dr. Harrold's substitute on the distinct understanding that they would be paid for at the rate agreed upon by the Brosna Dispensary Committee of Management, and charged on the rates of the electoral divisions comprised within that district."

DUNDALK UNION.

A DISPENSARY WITH A TAP ATTACHED.

THE following was read :—

"It has come to the knowledge of the dispensary committee at Clogherhead that a door has been open communicating with the waiting-room there, it is now ordered that the door be built up."

Dr. Adrian—What is Dr. Drew's complaint about it? I know something of what the requirements are.

Mr. King—Dr. Drew complains that it is not large enough.

Dr. Adrian—The Local Government Board requires that the waiting-room must be comfortable and large enough to accommodate as many patients as will come, and there must be a fire in it; two rooms are required.

Mr. Feehan said that the objection was that the back part of the waiting room opened into a public house. They considered it should be shut off from the public house.

Approved.

MULLINGAR UNION.

REFUSAL OF SANCTION FOR AN INCREASE OF SALARY.

A LETTER was read from the Local Government Board in reference to a resolution of the Board of Guardians of Mullingar Union of the 3rd Jan., proposing to increase the salary of the medical officer of the Mullingar Dispensary District, from £120 to £140 per annum. The Local Government Board desire to state that they do not see in the circumstances of this dispensary district, as compared with those of other dispensary districts in Ireland, a necessity for so large an addition to the salary of this medical officer. They approve, however, of an addition of £10 a year, making the salary for this district £130 a year.

DUBLIN CITY QUARTER SESSIONS.

HENRY CLORAN, a medical practitioner, sought to recover the sum of £8 from one Borden, for having attended the defendant's wife during her illness.

Dr. Cloran cross-examined—Did Mrs. Borden ever send for you?—She did.

Did you force yourself into her house?—No, her son came for me at night.

On your oath did you not pretend to cheapen goods in her shop, and then ingratiate yourself with her by asking after her family? (laughter)—I did not.

Did you intrude yourself into her house—did you hear that Dr. Kenny was in attendance upon her, and force your way in?—Never.

Did you meet him in consultation?—No.

Mr. Ennis said that at some future time a historian would describe the complainant as one of the most distinguished physicians in the city of Dublin, for having come here with, on this occasion, four suits, and on a previous occasion with 16 suits against his patients. The facts of the case were that the complainant came into the shop as if to purchase articles, then inquired about the woman's family, pretended to be a friend, and the defendant's wife thought she met the "good Samaritan" in the person of Dr. Cloran.

Mrs. Borden deposed to this effect.

An old woman deposed that on one occasion Dr. Cloran came to visit the defendant, who told him that Dr. M'Cormick and Dr. Kenny were attending her. Witness told him not to aggravate the patient, and ordered him out.

Dr. Kenny deposed that he had been attending Mrs. Borden.

Dr. Cloran—Had I known that he was in attendance, I would have been glad to meet him.

Dr. Kenny—And I would rather not (laughter).

The Recorder said that Dr. Kenny being in attendance, and Dr. Denham attending also, what did the woman want more? He should dismiss the case.

TIPPERARY GUARDIANS.

SUPERANNUATION.

MR. CROWE moved to superannuate Dr. Ryan of the Graine dispensary. He considered Dr. Ryan, from his long and arduous services to their Board for the past 26 years, fully entitled to such a remuneration as they thought proper to allow him, and believed from his present state of health, that he ought to be allowed the full amount of his salary.

Mr. O'Connell remarked that he was told by a professional authority that Dr. Ryan was in a bad way at present, and urged the necessity of giving the superannuation sought for.

Mr. Hogan—If that be so, what do we want giving him superannuation at all?

Mr. Brayden said he seldom attended the board, but saw and read the papers relative to this matter, and that Dr. Ryan paid £100 to Dr. White for his interest. As to the lease, the board had nothing whatsoever to do with it; it was made to Dr. Ryan, and was dated in the year 1856. Mr. Brayden further stated that the doctor was on his bed, dying fast, and he required some nourishment and a bit to eat, and described the proceedings as monstrous to treat a professional gentleman in such a way. He spoke as much for the interest of his successor as for himself.

Mr. O'Brien said the house was in the occupation of three or four doctors, and pressed for an adjournment of the proceedings for a month.

The Chairman said that Mr. O'Brien had no right to clog the matter by bringing forward his imaginary case about the house, with which the guardians had nothing to do.

It was then proposed that Dr. Ryan be superannuated in two-thirds of his salary, or £80, being the full sum to which he would be entitled.

Mr. Hogan opposed the motion, and regretted that he was obliged to do so in justice to the ratepayers, and said those doctors who were superannuated from time to time, were all sick, too; and he was told by old farmers that they were never so badly off, and the worse they are getting, the more we appear to be pressing the rates on them.

Mr. Quillinan proposed £50.

It was then agreed upon to withdraw the proposition for £80, and leave it to one poll of £50 or nothing; when there voted—For £50, 17; against it, 6.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE annual meeting of the Belfast branch of this Society was held in the Chambers, High Street, on the 6th February.

Dr. Moore, H.R.A., moved, and Dr. Higginson, Bangor, seconded, "That Dr. T. H. Purdon, the permanent President, do take the chair."

It was intimated that letters of apology, &c., had been forwarded from the following gentlemen:—Dr. M'Donnell, Randalstown; Prof. Redfern, Belfast; Dr. M'Bride, Gilford; Dr. Ritchie, the Grove; Dr. Ross, Belfast; Dr. Stewart, Donaghadee; Dr. Thetford, Strangford; Dr. M'Kain, Loughbrickland.

The President called upon

Dr. Wilberforce Arnold, Hon. Sec., who read the advertisement convening the meeting, and also the minutes of the previous meeting.

Dr. Drennan moved that the minutes be confirmed.

Dr. M'Gee seconded the motion, which was passed unanimously.

Dr. Browne, R.N., J.P., Hon. Treasurer, submitted the audited yearly statement of accounts.

Dr. Higginson moved that the report be adopted, which was unanimously agreed to.

The President, with Drs. Browne, Arnold, and Moore, H.R.A., were then unanimously appointed as a deputation to represent this branch in Dublin at the annual meeting of the parent Society, to be held in the Royal College of Surgeons in June next.

Dr. Bryce Smyth moved, and Dr. Beck seconded, "That the honorary collectors be cordially thanked for their services, and re-appointed for the ensuing year."

The motion was passed unanimously.

Auditors were then appointed for the ensuing year.

Dr. Browne intimated that he had received the following donations and subscriptions:—

Dr. T. H. Purdon, donation, £25; ditto, subscription, £5; Dr. W. Arnold, £2 2s.; Dr. Browne, J.P., £1 1s.; Dr. Ritchie, J.P., £1 1s.; Prof. Redfern, £1 1s.; Dr. Drennan, £1 1s.; Dr. M'Gee, £1 1s.; Dr. Gray, Castlewellan, £1 1s.; Dr. Higginson, Bangor, £1 1s.; Dr. M'Donnell, Randalstown, £1; Dr. Jamison, Newtownards, £1; Dr. Thetford, Strangford, £1 1s.; Dr. Stewart, Donaghadee, £1; Dr. H. Burder, Belfast, £1 1s.; Dr. Merrick, £1 1s.; Dr. James Moore, £1 1s.; Mrs. Harrison, Belfast, £1; Mrs. Stewart, Knock, £1; Dr. M'Bride, Gilford, 10s.; Surgeon M'Kain, Loughbrickland, 5s.; Dr. Bryce Smyth, £1 1s.

The meeting then proceeded to the election of its honorary office-bearers and committee of management for the ensuing year. The following were declared by the President duly elected:—

Hon. Secretary, Dr. Wilberforce Arnold; Hon. Treasurer, Dr. Browne, R.N., J.P. Committee—Drs. C. D. Purdon, Drennan, Ferguson, Harkin, J.P., Cuming, M'Cleery, Murney, J.P., James Moore, H.R.A., Alderman Whitaker, J. T. N. Smith, H. M. Johnston, John Moore, Bryce Smyth, M'Gee, and Spedding, with Drs. Musgrave, Lisburn; R. B. M'Clelland, Banbridge; Ross, Ballymena; Filson, Portaferry; Gray, Castlewellan; Higginson, Bangor, as country members.

Dr. Browne said that in the month of November last he had, in harmony with their resolution, addressed the students, and hoped there would be satisfactory results.

Dr. Browne moved, and Dr. Drennan seconded, "That this meeting thankfully acknowledges the influential advocacy our Society has always received from the press of Belfast, and relies on a continuance of its powerful co-operation."

The resolution was passed unanimously.

The remaining business having been transacted,

Dr. Arnold moved that the President do leave the chair, and that Dr. Browne do take it, and that the marked thanks of this meeting are due, and are hereby tendered to the permanent President (Dr. T. H. Purdon) for his proper and dignified conduct in the chair.

Dr. Bryce Smyth seconded the motion, which was passed amid applause.

The meeting then separated.

YEARLY SUMMARY—1877.

(Continued.)

Bronchitis proved fatal in as many as 1,388 instances, pneumonia in 510, asthma in 19, pleurisy in 18, laryngitis in 7, and lung disease unspecified in 147; the total deaths from these causes being 1,889, or 60 in every 10,000 of the population, against an average rate of 49 per 10,000 fer the preceding ten years, the mortality in 1877 being heavier than that in any of those years.

Diseases of the heart and circulatory organs caused 452 deaths, classed as follows—pericarditis 4, aneurism 38, and heart disease 410; the deaths from these causes are 59 over the annual average for the ten years 1867-76.

There were 182 deaths attributed to paralysis, 123 to apoplexy, 51 to cephalitis and its membranes, 38 to epilepsy, 10 to insanity, 3 to chorea or St. Vitus's dance, 157 to brain disease unspecified, 12 to jaundice, 5 to hepatitis, 122 to liver disease unspecified, 1 to spleen disease, 50 to nephria, 9 to diabetes, 8 each to nephritis and cystitis, 2 to stone in the bladder, 1 to ischuria, and 78 to kidney disease unspecified.

Provincial Town Districts.—The only death from small-pox returned during the year by any of the Registrars for the seven provincial town districts included in the Summary is one which was registered in Belfast in the September quarter.

In Limerick, according to the weekly returns, there were registered 49 deaths from diarrhœa, 29 from fever, 23 from scarlatina, 4 each from measles and whooping-cough, and 2 from diphtheria, these 111 deaths being equivalent to 2·5 per 1,000 of the population.

STATISTICS OF RELIEF AND EXPENDITURE.

Local Government Board, Dublin,
2nd January, 1878.

SIR,—The Local Government Board for Ireland transmit to you herewith, for the information of the Board of Guardians, a copy of a Statement, which has been prepared in anticipation of the more detailed information to be given in the Board's next annual Report, showing the collection and expenditure of the poor rate, and the number of persons receiving in-door and out-door relief in all Ireland, during the year ended 29th September, 1877, in comparison with the same particulars for the precedin year.

By order of the Board,
B. BANKS, Secretary.

To the Clerk of each Union.

The following statement of expenditure has been prepared in anticipation of a similar statement prepared after audit; and is, therefore, not strictly correct. It will, however, be found to be a close approximation to the actual expenditure.

It will be observed that the total poor rate lodged amounts only to £878,797, while the total expenditure under all heads is £1,045,681, being an excess of expenditure over poor rate of £166,884. This deficiency is, however, nearly met by a sum of over £93,000 received from the Parliamentary Grants in aid of medical and educational expenditure of salaries of officers under the Public Health Acts, and over £27,000 received by the unions from other sources.

The statement does not show the numbers who received relief under the Medical Charities Acts; the cost of which is given in column 6 as £141,157. The numbers so relieved may, however, be roughly estimated at about 770,000.

EXPENDITURE AND POOR RELIEF FOR THE YEAR ENDED THE 29th SEPTEMBER, 1877.

Provinces.	Poor Relief Expenditure.				Expenses under Medical Charities and Vaccination Acts.	Expenses under the Acts for Registrat'n of Births Deaths, and Marriages. ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 128.)

HEREDITARY SYPHILIS.

The question we have first to consider is: Was this child the subject of hereditary syphilis or not? We have only direct proof of this from the history of the case. Suffice it to say that the mother had several miscarriages, that all the children, and this one in particular, were extremely delicate, and if we had no further evidence than the pathology, it would be quite enough to set our minds at rest. It will, I am sure, occur to some that if these lumps in the brain, and the changes in the cerebral vessels, were really due to syphilis, why should there have been a large amyloid liver, and a similar condition of the kidneys, when gumma might have existed. Again, how much more likely is it for scrofulous masses in the brain to be associated with amyloid viscera than gummatous growths.

But universal gummatous degenerations are rather the exception than the rule in advanced syphilis, and especially in broken-down constitutions. This does not substantiate the doctrine of want of symmetry which Mr. Hutchinson wished to establish as a sign to indicate that syphilitic manifestations in the tertiary period were not due to a blood disease, neither do I in any way wish it to do so; for as long as there is anything in blood or tissue, let it be syphilis or its sequelæ, so long have we a general constitutional condition to deal with, and not a purely local manifestation. A weak point, however, may exist, or what in other words may be understood as the susceptibility of an organ from hereditary or constitutional predisposition, and on which syphilis, like any other blood poison, exerts a determining and specific action. Hence we find the brain to be the seat of syphilitic change in some; the lungs, the heart, the liver, the spleen, and kidneys in others; and I can only repeat the statement expressed elsewhere that the poison of syphilis, when found to have germinated in the nerves or nervous centres, is not, as a rule, associated by a reciprocity of kindred action in the thoracic and abdominal viscera. The reverse of this is the case in nodular periosteal and cario-osteal syphilitic manifestations, and we might say that amyloid fibroid or gummatous visceral changes are always more or less associated with them.

The next example of hereditary syphilis is one which claims for itself an especial consideration. At the beginning of last year, I was consulted by a lady concerning her child, a little boy of 15 months old; he had been under medical care, and had taken steel wine, cod-liver oil, chemical food, raw meat, and such like. He was one of seven children, the rest of whom were healthy, but the teeth of all were irregular, and not notched. At birth, this child did not snuffle, but two months after it was covered with some eruption. Beyond this, it grew proportionate to its age, until it was nine months old. At this time teething commenced, and with it a series of epileptic seizures. The child now lost flesh, its power of assimilating nourishment almost completely failed, and general functional derangement of necessity ensued. When he first came under my care, the most noteworthy feature was the excessive cranial development, with want of closure of the anterior fontanelle. Some five or six teeth had just made their escape through the gums. The hair was scant and fine, the eyes clear, and there was no sign whatever of ocular structural defect, except some haziness around the margins of the optic discs. There was a marked want of co-ordinating power in the ocular muscles, but the features were not so stunted as one often finds them to be, the gums were not spongy, the voice was weak and croaking, and there was that constant movement of the lips upon each other, with dribbling of saliva, which is somewhat indicative of micro-cephalic disease. Automatic co-ordinate movements of the upper limbs were performed, but not of the lower,

there was no power to stand or even to sit up in bed, Electro-muscular contractibility was normal. There was no spinal or thoracic distortion. The respirations were regular, but the deepness of certain inspirations equivalent to a yawn were noticeable. The spleen was considerably enlarged, but not so the liver. The bowels acted very irregularly, sometimes relaxed at others constipated. The evacuations were acid; unhealthy, and of a pale colour. From the examination, it was evident that the child had hydrocephalus, but it was not quite clear as to its origin. Yet the following evidence, and the result of treatment, will, I hope, supply any missing link.

I have stated that the child was the last of seven, the others being quite healthy and free from any of the usual signs of syphilitic taint. Some months previous to the birth of this last child, the parents met with serious pecuniary reverses, and were reduced from a position of affluence to one of almost poverty; and great mental depression on the part of the mother was the result. The father contracted syphilis when he was a young man. At the time of my first seeing this child the mother was complaining of not having been well for a long while. She often suffered from sore throat and nocturnal headache. One thing, however, was quite conclusive to my mind of the existence of syphilitic taint, and that was the well marked bi-lateral psoriasis of the tongue. Upon this evidence I commenced to treat both mother and child energetically and thoroughly for syphilis. For the former I prescribed 1-12th gr. of bichloride of mercury with half-a-grain of sulphate of iron, and one grain of extract of nux vomica in the form of a pill, to be taken three times a day. These were continued for three months, when her health was completely restored. For the child I ordered the mercurial ointment to be rubbed into the axillary, submaxillary, and Scarpa's spaces every night, and a hot bath of iodide of potassium and common salt to be used every other morning, and in which the child was to be completely immersed. Cod-liver oil was given. I had used a similar treatment to this in several cases with success where I had suspected syphilis, but in the case here quoted, its specific action was so progressively marked, that any suspicion I might have entertained as to the etiology of the hydrocephalus was completely set aside. In three weeks the spleen was reduced to its normal size, the bowels acted regularly, the evacuations were natural in colour and consistence, the child retained its food (which, by the way, was ordered to be of the most simple character), the convulsive fits with the startings at night had ceased, and the child, much to the mother's delight, was in a fair way for recovery.

The treatment was continued for three months most persistently, and at the end of that time the more important features of the disease had subsided; the head had not increased in size, but the body had in proportion to the child's age, the outline of the optic discs was clear. Automatic and voluntary acts were performed co-ordinately in both arms and legs, several fresh teeth appeared which were normal in type and regularity, the child could walk unaided, and the vocal resonance was normal. I saw this child very recently, it was then over two years old, and there was no return of the brain symptoms. The faculty of speech was backward, but becoming gradually developed, and he bids, as far as I can judge, to be a well conditioned and intelligent being.

With regard to this case, I feel confident that no form of treatment but that adopted, could have saved the child from becoming a helpless hydrocephalic monstrosity, and what I have especially to urge is: That we are quite unable in many cases to gain the slightest clue either from signs, symptoms, or history that our little patients are the subjects of syphilis; and in this case I maintain that it is our positive duty, no matter how far emaciation has advanced, not to neglect the thorough and complete use of anti-syphilitic remedies. I have yet one case more to add, namely, that of a little boy, aged seven years, who came under my care. His father had been a soldier, but died, it was said, of phthisis. His mother was a fair, strong, healthy-looking woman, who stoutly denied having any syphilitic taint. However, she complained of failing sight; sometimes objects would look double, at others she could scarcely see at all. Upon ophthalmoscopic examination, there were the remains of syphilitic retino-choroiditis, with black pigmentary patches to be seen. She also consulted Mr. Liebrich and Mr. Hogg, both of whom prescribed anti-syphilitic remedies; and the question of course came into my mind how far her child's diseased condition arose from syphilis. To be very brief, his state was as follows: He was a delicate child from his birth. Was not known to have snuffled. He was late in teething, walking, and talking. At four years old he was covered with an eruption upon the skin, and soon after this there was a discharge from both ears, associated with epileptic convulsions. When I first saw him there was angular curvature of the spine in the dorsal region with multiple sinuses, and discharge from both ears, an interstitial keratitis of both eyes, very irregular, ill-developed teeth, without notching, enlarged submaxillary glands, and great emaciation. The liver and spleen were large and amyloid. The head was well formed, and the facial expression not indicative of either syphilis or scrofula. Yet we have a clear enough proof of syphilis, and under ordinary circumstances, we should have designated the boy's condition as scrofulous. He certainly improved most under anti-syphilitic treatment; and my opinion is that it was the result of syphilis; but I am sorry to say that of this I have no further proof, as the child died rather suddenly of erysipelas, and no *post-mortem* examination was made.

It is interesting to find that within the last few years our knowledge of diseased states by pathological investigation—I mean more particularly in reference to their intrinsic nature—has become more widely extended and established upon a more solid basis than ever before existed; and if we compare the noteworthy discussions which have been held on the pathology of tubercle, cancer, and syphilis, I think no one can contemplate the vast collection of facts which were brought forward without feeling that the rapid strides which have been made concerning the nature and results of syphilis, far outbalance, and are of much greater practical importance, than those of either cancer or tubercle.

It is to the future, however, that we have to look for the development of those investigations which are by comparison mere embryonic germs; and I am sure that even the greatest sceptic must feel proud of the grand position which pathology is beginning to hold in this country, and wish every success to those who devote themselves to unravelling its mysteries.

Hornsey Lane, W.

(To be continued.)

THE TREATMENT OF "AFTER-PAINS."

By BERNARD KELLY, M.D.,
Medical Officer of the Fifth District of St. Olave's Union, Southwark, &c.

I HAVE always, since I have known anything of practical midwifery, deemed the hasty interference with after-pains as highly injudicious. What labour-pains are directly to the fœtus and placenta, the after-pains are to the mother. Let either be incautiously tampered with, and danger will almost inevitably ensue. Now, let us ask ourselves the question, What purposes do the after-pains fulfil? That they expel clots remaining in the cavity of the womb, and reduce the organ to something like its ante-gravid state, and prevent, if not check, uterine hæmorrhage, there can scarcely be a rational doubt. They also seem to be a continuation of the natural labour-pains, and, as such, tend towards gradually expending the nervous energy centred in the uterus, but more especially in the hypogastric plexus of the great sympathetic; and ought, therefore, not to be lightly interfered with, or suddenly suppressed.

The wombs of primiparæ, as a rule, being endowed

with greater tone and muscular contractility than those of multiparæ, resume more quickly their natural dimensions and position in the pelvis; indeed, they may be said to do so almost directly after the labour is ended. Hence the general absence of after-pains in the case of the former, and their very great frequency in that of the latter class.

If after-pains are due to the presence of clots in the cavity of the uterus (which, however, I very decidedly doubt), then Nature provides a remedy in uterine action which removes them far more effectually, and with much less risk and danger to the mother than can the hand of the accoucheur; which, to say the least of it, is a very cumbrous and repulsive expedient.

And now as to the treatment. If after-pains are a continuation and supplement, as I believe them to be, of the normal parturient process, then the less we meddle with them the better. This expectant method I have found in the great majority of cases to be both safe and strictly correct. It is only when they continue unusually long, and are very severe, that remedial measures are called for. Here I have found small doses of opium frequently repeated, when no uræmic complication co-existed, combined with an alkali or acid, as either was indicated, to answer an excellent purpose. This plan I consider much safer than giving the drug in a single large dose, which has a tendency to suddenly paralyse nervous action, and to subsequently lead to passive enlargement and congestion of the uterus. This objection derives additional force from the occasional presence (often unsuspected by the young accoucheur) of albumen in the urine, and the consequent danger of uræmic convulsions; when, if a large dose of the narcotic be blindly administered, fatal effects will almost inevitably follow. Here there is no remedy to compare in safety and value with the old-fashioned tincture of iron, which may be given, properly diluted, in large doses and *ad libitum*. When pains, unattended by uterine action, follow labour (which, in my experience, is very rare, unless as the prodromata of puerperal peritonitis), why then ergot may be advantageously prescribed. But, to exhibit it in cases where the viscus is already, so to speak, madly in action, would be simply applying spurs to the willing horse. In dealing with this affection, we should ever be guided by coolness and common sense; and bear in mind the apothegm of a great authority on the subject, "Meddlesome midwifery is bad."

SOME PRACTICAL REMARKS ON AURAL AFFECTIONS.

By H. Macnaughton Jones, M.D., M.Ch., F.R.C.S.I. and Edin.,
Surgeon to the Cork Ophthalmic and Aural Hospital, with Special Throat Department.

(*Continued from page 29?, last vol.*)

CRETACEOUS DEPOSITS ON THE MEMBRANE.

These deposits occur occasionally and are easily recognised. They appear as white layers of chalky substance on the membrane, which is generally also altered in shape, perhaps adherent to the tympanum. They may exist without much disturbance of hearing, and often are to be found in one ear only. A lad of 18, whose hearing in the left ear was normal, consulted me for obstinate deafness in the right ear. The two pockets were covered with irregular shaped white masses of a chalky substance. The tuning fork was heard less loud in this ear, and inflation of the membrane gave a dry sound. A drawing of this case, and others of the same nature, I have included amongst those I have selected for an Aural Atlas now in course of publication. An officer recently came to me, complaining of constant tinnitus in the right ear. The deafness had lasted for ten years; was rather worse of late; he had been twelve years in India; the tinnitus commenced after his return home, and the deafness grew worse. There never had been pain; there was no family history of deafness. The watch was not heard on contact. The membrane had a cretaceous mass in the superior pocket, and on inflation there was a dry and grating sound. The tuning fork was heard only in the left ear, whether placed on the head or the teeth. He suffered from giddiness at times, and had then a tendency to fall. When the secretions were irregular, or that he was "bilious," the tinnitus, he said, became much worse. Nothing relieved him. Hydrobromic acid and bromide of potassium cured the giddiness, but the tinnitus did not yield to any treatment. Hinton, in his remarks on the climate of India, notices the susceptibility of residents of that country to the influence of quinine. In these persons, he says, "loss of hearing without visible affection of the tympanum is very frequent." So also he notices the tinitus, which becomes worse on return to England, and remarks that children born in India, "who have lived there during their first years, seem subject to become deaf with no visible cause as they approach the age of puberty." I have been consulted by several officers who have returned from India with incurable deafness and tinnitus. In nearly all the cases there were evidences of old catarrh in the tympanum, and consequent changes in the membrane and ossicles.

EUSTACHIAN OBSTRUCTION AND CLOSURE.

If we were to study all the various diseases of the ear, which follow any of the abnormal conditions of the Eustachian tube, we would find that this passage, its healthy or unhealthy state offers to us a clue to the causes of by far the largest proportion of aural complaints.

I must therefore be satisfied here with dealing briefly, but practically, with a few of the abnormal conditions of the Eustachian tube. The original causes of Eustachian closure may be simply cold "caught" in any way; exposure to draughts, damp, rheumatism, sea-bathing, exanthemata, severe mental shocks, &c., are some of the most frequently assigned. During a cold, every one is familiar with the sense of stuffing in the ears, and perhaps muffling of sounds or tinnitus which accompanies it. On examining the throat, we may find the mucous membrane swollen or turgid; perhaps the uvula is enlarged, or the tonsils are hypertrophied. The faucial orifice of the Eustachian tube is likewise swollen; and in consequence there is temporary closure of the passage, and mucus is imprisoned in it. It is when this condition persists for a little time, that we see the characteristic membrane of Eustachian closure. Little air enters the tube, and a partial vacuum is formed in the tympanum, which results in an increased concavity of the membrane. Hinton says this form of membrane is characteristic of Eustachian deafness. "The malleus appears foreshortened, and the membrane has a tense stretched look, like a drawn curtain, often falling into similar folds. The colour varies, is generally white and dull, but sometimes, especially in the earlier stages, the congested mucous membrane of the tympanum shines through it." When inflation is resorted to, we hear the sound with the otoscope either not at all, or with great difficulty. Now this simple swelling of the Eustachian tube, which at first may be periodical and remittent, may finally become chronic and permanent, beginning with a slight deafness, and perhaps a little earache; it may or may not be a considerable time, dependent to a certain extent, whether the mischief appertains to one or both ears, before troublesome deafness, accompanied with tinnitus, occurs. Nothing in the whole range of medical practice, is more astonishing than the extent to which persons permit aural mischief to proceed before they seek relief. This is the more remarkable if only one ear be affected; often it is the incessant noise in the ears which forces them to apply, and not the deafness. If the closure and obstruction lead to other results, say acute inflammation (catarrh) of the tympanum, and perforation of the membrane, as it frequently does, then they apply for relief of the pain and other symptoms which accompany it. If it does pass into this chronically contracted or permanently closed state the most serious results follow.

The slight catarrhal inflammation, which is the consequence of the primary affection, leads to an accumulation of mucus. This mucus increases in quantity and is imprisoned. It may become hardened and form hard masses both in the tube and the cavity of the tympanum, about the chain of ossicles, and on the membrane. A collapsed and closed Eustachian tube, leading to imprisonment of mucus, abnormal concavity of the membrana tympani, followed later on by alteration in the shape and appearance of the latter, adhesions, anchylosis of the ossicles and hardening of the mucus, are the usual effects which ensue on a common cause, viz., a catarrhal state of the naso-pharyngeal mucous tract.

In the treatment of all conditions supervening on a closed or obstinate state of the Eustachian tube, the first object is to secure its patency. The method of doing this I have already dwelt on. Catheterisation, assisted if necessary by ordinary or laminaria bougies (very fine) about half a line in diameter for the narrowest part of Eustachian (Hinton). If a laminaria bougie is used in addition to the catheter it must not be left in longer than 20 minutes. The bougie is passed through the catheter, which is put in first, and the catheter is withdrawn before the bougie. I seldom now use any bougies. Various sizes of the latter may be introduced through the catheter, which then can be withdrawn with the bougie, and so we may prevent its being broken in the passage. I have never had a case of a foreign body (except snuff) blocking up the tube. I rely mainly in most cases of Eustachian closure on warm iodide of potassium injection, and frequent Politzerisation. The nasal douche of salt water, previously alluded to, is often of great benefit. But constantly we meet patients who cannot use the syphon douche. Then the simple sniffing up of a warm solution of salt is a capital substitute. I generally direct about an egg-spoonful to two wine-glasses of tepid water, used once daily. If acute perforation occurs from closure of the Eustachian tube, we must be satisfied with gentle washing out of the tympanum daily with a warm solution of chloride of ammonium, while we attend to the inflammatory condition of the membrane by warm fomentation, gentle syringing with anodyne and alkaline washes, leeches or vesication. I exhibited recently, at the meeting of the British Medical Association, a collection of water-colour drawings of the different diseased conditions of the membrana tympani, accurately taken from nature at the Ophthalmic and Aural Hospital. Amongst these was one typical of a class of membrane frequently found as the result of closure of the Eustachian tube and accompanying this condition. The membrane had that characteristically thin appearance seen in complete collapse. On inflation, the lower portion of the membrane was blown bladder-like out. The upper part and malleus were bound by adhesion down to the inner wall of the tympanum. Hinton graphically describes this state under the head of "Collapse and Rigidity of the Membrane," and he notices the fact, illustrated in the above-mentioned case, that the hearing power is often good. He advises, when the membrane lies in contact with the tympanic wall, the application of the artificial membrane. Suction of the meatus, as recommended by him, I have frequently found of service in these collapsed conditions of the Eustachian tube. This is best effected with the pneumatic speculum, through which we can at the same time see the adhesion and the extent to which the membrane and malleus are adherent. But it is a good plan to give a patient a piece of tubing with a quill inserted in one end to fit the meatus, and instruct him to apply suction with the mouth through the other. This plan of suction and inflation practised by the patient himself may be followed up by incision of the membrane, or in rare instances (Hinton), an attempt may be made to restore the malleus to a normal position, and by so doing, we free the stapes. This, however, is a step not to be lightly undertaken, as it requires the most delicate manipulation to cut round the adherent malleus or stapes, and raise them by the gentlest of pressure into a better position. Politzer's plan of "air-tight closure" of the malleus when the membrane has been well inflated, may be found useful in these cases of collapsed membrane. A piece of cotton wool is rolled into a ball with some cord or softened wax, and after a powerful inflation of the membrane, the meatus is plugged with the ball. This the patient can do himself, wearing the ball at night and periodically omitting it.

THE MASTOID CELLS.

In various catarrhal states of the meatus and tympanum, the inflammation may spread to the mastoid cells and to the brain. The cerebrum and cerebellum may be attacked, more frequently the latter if the case be that of an adult. There are many cases which give rise to inflammation and abscess of the mastoid process. The exanthemata, injury, abscesses in the meatus, catarrh in the tympanum, polypi, scrofulous inflammation, all may, both in children and adults, lead to abscess in the mastoid or mastoid periostitis. The periostitis which accompanies these catarrhal states of the meatus, and which at times occurs independently of them, is marked by characteristic symptoms. There are frequently severe constitutional accompaniments, such as rigor, rapid coating of the tongue, quick pulse, increase of temperature, with severe pain. The post-auricular and supra-auricular regions become red and swollen. The rapidity with which the swelling occurs is often alarming. In a case I had of severe furunculous inflammation in the meatus, the entire side of the face and neck became swollen in forty-eight hours. The swelling has then an erysipelatous look. I have never yet seen a case of mastoid periostitis or abscess where the meatus and tympanum have not been involved. The sterno-mastoid has only been implicated in one case. Turnbull notices that this implication of the sterno-mastoid is not probable when the inflammation is intense. Here we are more likely to have caries and post-aural opening. If the inflammation runs its course, it may cause suppuration, and the pus will find its way out either by the external meatus or through the mastoid process. Bearing in mind the anatomy of the bony parts, it must be a matter for surprise that the mastoid cells escape as frequently as they do, when the tympanum is affected. Still there can be little doubt that this spreading of the inflammation does frequently occur, and often is not suspected. Purulent or hyperplastic formation may take place in the mastoid cells, especially in children, and no external evidence exists of this occurrence. It is surprising how often in children, especially of the poorer classes, extensive bone changes may go on in the mastoid, leading to softening, necrosis, and caries, with but little indication of the danger, and consequently a degree of excusable neglect on the part of the parents. In a short paper on "Hyperostosis of the Mastoid Process," by Dr. Orme Green, of Boston, and published in the "Proceedings" of the Otological Society (1877) of New York, the author divides the results of periostitis in the interior of the mastoid cells thus:—1. *Formation of pus and resulting abscess.* 2. *Extension of the inflammation by the minute vessels in the osseous foramina to the external surface of the mastoid.* 3rd. *Ostitis,* this latter being purulent or hyperplastic—purulent, leading to perforation with consequent absorption of the entire osseous structure or of the calcareous particles alone, or, it may be, to complete necrosis or caries; hyper-plastic, causing new periosteal bony formation, and resulting hyperostosis, and perhaps finally obliteration of the entire mastoid cavities by new bone. He illustratas the advantage in these cases of perforating the mastoid process, when accompanying brain symptoms prove the extension of the inflammation to the brain. Mr. Hinton, in referring to this subject, says "the most scrupulous care should be given to detect any symptoms of the presence of matter pent up under the periosteum. This is generally found in one of two lines—either over the mastoid process, externally, or

within the meatus at the posterior and upper wall. Any redness or swelling with tenderness of these parts should prompt immediate action." He points out that free incision of the posterior and upper wall of the meatus will often give great relief. In using the trephine Mr. Hinton says, "the best point to select is a spot level with the upper border of the meatus, and about half-an-inch beyond it; the perforator may be allowed to penetrate three-quarters of an inch." "It is, he says," of the utmost importance not to delay too long, and since the ether spray will generally suffice to deaden the pain, incision of the mastoid may be had recourse to promptly in every such doubtful case. I may repeat that I have never regretted making the incision, and scarcely ever decided against making it without regretting that I did not." I thus prominently draw attention to this opinion, as I am aware that this is a step which is regarded with fear and a good deal of prejudice by those who are not familiar with the harmlessness of the operation, and the good results which frequently follow. On a few occasions I have in vain urged the propriety of making an experimental perforation of the mastoid process by the trephine when urgent brain complications were present, but the fear of the operation and its direct results prevented this step being taken. In both instances I can only regret that it was not done, as death from brain trouble ensued, and the refusal of an autopsy prevented my ascertaining the cause of the fatal termination of the case. In a few instances in adults free incision over the mastoid when there were signs of periostitis has been followed by the happiest results—complete subsidence of the pain and inflammation. In children incision down to and through the bone is the thing indicated when there are evidences of extensive periostitis or purulent formations.

To illustrate how Nature demonstrates the course of action indicated in these cases, I may cite the following instance of escape of bone through the external meatus, with relief of brain symptoms.

In 1875, a child, aged 4 years, was brought to me with the following history: He had been quite healthy up to a few months since, when pain in the ear and discharge began. Subsequently an abscess formed over the mastoid process. The child had two or three attacks of convulsions. On examining the ear I found the post-auricular surface soft and swollen, the meatus full of purulent and foul-smelling discharge. I cleaned this well out, and was surprised to find the meatus filled with a piece of loose and dead bone. This I removed, incised freely the mastoid process, kept the incision plugged with iodised wool. This I cleansed with carbolic lotion daily, washing out the meatus with the same. The child made a good recovery, but with loss of hearing.

In April last a young lady consulted me. The right mastoid process was completely absent, a large hollow existing. This had occurred when she was a child, and was the result of mastoid abscess, yet she had fair hearing power in the right ear.

Last year a child, aged eighteen months, was brought to this hospital with large perforation of both mastoid processes. I freely incised the bone at either side, and almost the entire of the mastoid process came away at the time, being removed easily with the forceps. Some time afterwards she came in my absence from home, and the other mastoid process had softened, and now came away. The child became quite healthy. Here I syringed freely through the external meatus a disinfectant solution, such as chloride of zinc, Condy's or carbolic acid, the fluid running out through the aperture in the mastoid. The parts have all now completely healed, and the child was recently brought by the mother to consult me about the hearing, which is lost.

Early this year a pale, anæmic-looking child, aged twelve months, was brought to the hospital with ptosis of the right eyelid, dilated pupil of the same eye, and the vision apparently lost. There was a considerable swelling of the entire left aural region. The mastoid was very much inflamed, soft, red, and swollen; the auricle was projecting. Altogether the child had a most peculiar appearance. There issued from the meatus a foul and long-neglected discharge. The skin behind the auricle was perforated in two or three places, and the bone was evidently dead underneath. I determined to make a free incision into the mastoid, which I did, and though, at the time, there was very formidable hæmorrhage, this was readily controlled with a plug and compress. The ear was daily daily washed out with chloride of zinc injection, and the mastoid dressed with carbolised wool saturated with chloride of zinc solution. Under this treatment the child did well, but the ptosis and strabismus remained. With the ophthalmoscope there was but little evidence of any abnormality, the only thing apparent being a hyperæmic state of the papilla. Lately this child came to the hospital when I was absent on my holiday trip, and a large piece of the mastoid came away, the wound being treated as before.

ECCENTRIC, IRRITATIVE, OR REFLEX ALBUMINURIA.

By Dr. G. de GORREQUER GRIFFITH,
Senior Physician to the Hospital for Women and Children; Consulting Physician-Accoucheur to St. Saviour's Maternity.

In the Medical Press of January 23, 1878, under the heading, "Albuminuria of Nervous Origin," appears the following:—

"M. Tessier, of Lyons, thinks that albuminuria is more often of nervous origin than is generally supposed. There are, indeed, many facts to show that nervous phenomena frequently precede the albuminuria, and that they may be considered to have have some casual connection with the disease, receives some confirmation from the experiments of Claude Bernard respecting the production of albuminuria by lesions of the fourth ventricle."

In the January number of the *Practitioner* I published a short paper on "Eccentric, Irritative, or Reflex Albuminuria," and at the 1877 meeting of the British Medical Association a paper by me was read on the same subject, in which the following words occurred, and, as I have had no reason to change my opinion, I will here transcribe the part of the paper to which I refer:—

"In a most suggestive paper on 'Albuminuria,' read before the Medical Society in March, 1877, Dr. Lauder Brunton described the true and false forms, as he termed them."

In the discussion which followed, I then briefly alluded to the case, subsequently published in the *Practitioner*.

Some years ago I was called in consultation to the wife of a now eminent barrister; she was in labour with her first child; the os was rigid and unyielding; the pains had been teazing and sharp, yet apparently productive of not much good as regards forwarding the birth; the patient, though of hopeful, sanguine temperament, was now fretted, irritable, and restless, yet not at all alarmed about her state.

The first attack of convulsions had passed off previous to my being summoned, and consciousness had returned when I saw her. As it could not be satisfactorily determined whether she had passed water, I introduced the male catheter, and drew it off, there being only a little in the bladder. After her next convulsive seizure she remained insensible, and continued so, between the times the convulsions would come on, nor would at all wake to consciousness. We examined the urine, and found it loaded with albumen; this was looked upon as a fatal symptom; delivery was impossible owing to the state of the os, but I encouraged the medical attendants to continue watching by her bedside, and to deliver her (if necessary) with instruments at the very earliest opportunity, rather than allow the labour to be protracted, for I believed the albuminuria to be coincident with the fits, but not the cause of them, and that its appearance

arose from the enormous disturbance of the entire system from the local irritation going on (the process of labour I meant), and from the consequent local renal congestion, which I had no doubt supervened, and which would account for the small quantity of urine.

There was no history of any manifestation of renal mischief prior to the lady's falling in labour.

I was hurriedly called up next morning, the os had dilated, the child was being born, the obstetric instruments I brought with me were not even needed, as the birth was soon accomplished, though during the exacerbation of a paroxysm of convulsions. I removed the afterbirth at once, so as to get rid of all sources of irritation as speedily as possible. The mother, however, still lay unconscious.

I now advised painting the back of the neck with the acid nitrate of mercury, and after agreeing in consultation, I proceeded to act on the advice.

This began to give pain little by little, till it produced the acme of pain and counter-irritation, when the patient awoke. All traces of albumen in the urine were gone when we next examined, and now the lady is a good specimen of a British woman, and is the happy mother of five children.

From this I learned much, and regarding it as a case truly of reflex, eccentric, or irritative albuminuria, purely intermittent, I dealt with it as such, and my hopeful prognosis was not unavailing. I am confident, many cases will be met of this form of albuminuria, and that, if recognised, we may save our patient; if overlooked, we may let her slip from life to death.

I think that puerperal albuminuria, coupled with convulsions, arises rather from the great nervous disturbance, especially the local; and from the *consequent* renal congestion and condition of the entire renal system, than from that condition of the blood which obtains in, and is we may say natural to, the puerperal state. Were these latter the sole factors of the convulsions and albuminuria, albuminurial puerperal convulsions would arise more frequently. I consider these cases of puerperal albuminurial convulsions to be eccentric, irritative, or reflex, the local or uterine disturbance being the originating agent.

Clinical Records.

ST. MARY'S HOSPITAL.

Urethral Fistula.

Under the care of Mr. HAYNES WALTON,

Surgeon to the Hospital.

A MAN, aged 30, was admitted in this state. Half-an-inch to the right side of his anus was the mouth of a sinus, through which a probe could be passed and carried superficially inwards to the back of his scrotum. A slight leakage of urine through the sinus attended each natural evacuation of the bladder.

His history told that twelve months before his admission a small abscess burst in the perinæum, and soon after urine escaped, and has continued to run out. He denied that he had had any evidence of stricture, or that he had been subject to any cause which could produce such.

Mr. Walton ordered the patient to be taken to the operating theatre, explored the urethra with a metallic catheter, and pronounced the existence of stricture in its membranous portion, but yet not a severe one, as he passed a No. 7 instrument into the bladder. He spoke, too, of the case being favourable for treatment, because there seemed, as yet, no bladder irritation. He slit open the perinæal sinus, and tried in vain to find the course by which it communicated with the urethra. A soft catheter was introduced, tied in, and a narcotic administered per anum. But rigors and other symptoms of constitutional irritation set in furiously on the second day, and the catheter was taken out, but the urine was drawn off three times in twenty-four hours.

At the end of sixteen days the superficial perinæal sinus had healed, and but a short fistula remained, which was cauterised with nitrate of silver. The stricture was so relieved that a No. 10 metallic catheter could be easily passed, and if the patient only pressed on his fistula when he micturated naturally he effectually prevented the escape of urine. However, the treatment was only partially successful, as the fistula was still there. Mr. Walton determined to lay open the urethra freely through the perinæum. It was evident that the fistula entered the canal laterally, but its passage could not be traced with probe or fine wire. A grooved staff was introduced into the bladder. Mr. Walton cut through the urethra in the middle line, a little posterior to the fistula, to the extent of an inch. A metallic catheter was kept in the bladder for a day, and then introduced for a few minutes every second day. In a fortnight the perinæal wound had healed, and with it the fistula. The patient left the hospital quite well.

The whole *rationale* of the treatment consisted in preventing, for a time, the escape of urine through the fistula, whereby the false passage was afforded rest from an irritant, by which only it could heal. For this purpose dilatation of the stricture was necessary, and, as it proved, division, also, of the urethra.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the last meeting of this Society Dr. VIVIAN POORE read a long and exhaustive paper on "Writer's Cramp and Impaired Writing Power," of which the following is a brief extract. The paper was founded on an analysis of 75 cases, which the author divided into six groups—1, paralytic (6 cases); 2, spasmodic (5 cases); 3, degenerative (9 cases); 4, neuralgic, or neuristic, (19 cases); 5 writer's cramp (32 cases); 6, anomalous (4 cases). It was remarked that as the ulnar nerve supplies 13½ out of the 18 intrinsic muscles of the hand, its integrity is necessary for all delicate manipulations —especially writing. The spasms which affect the hand in paralysis are sometimes owing to faulty antagonisation among the muscles of the paralysed limb. In these cases we should look to the peripheral aspects of the question, as well as to centric causes. There will be no spasm when the nervous impulse, issuing from the brain, is distributed to equally irritable muscles, but if the equilibrium of antagonisation is disturbed by secondary lesion the production of spasm is easily conceivable. Loss of writing power is often the first and most prominent symptom of degenerative change occurring in the spinal cord or brain. The neuralgic group may be induced solely by overwork, or by strains and other injuries, combined with exposure to cold and bad health. It is often difficult to distinguish this group from true writer's cramp, but the neuralgic variety involves a wider area; it is sometimes induced without excessive exercise of any function, and the neuralgia is a prominent symptom. In the group of true writer's cramp considerable care is necessary to detect peripheral evidence of mischief, but the author states that in every case of impaired writing power which he has seen *there has been evidence more or less marked of derangement of one or more of the muscles used for writing.* This evidence consisted of—first, obvious failure to use certain muscles efficiently, either for writing or for some other less complicated act; secondly, the occurrence of consentaneous movement or tremor when certain muscles were put in action; thirdly, depressed or exalted electric irritability; and, fourthly, the occurrence of sensory derangement, or nerve tenderness. The muscles which are most frequently involved are those of pen-prehension and pen-movement. Reviewing the cases as a whole, attention is directed—first to the inferences which may be drawn from an inspection of the hand-writing; secondly, to the fact that joints were found to be implicated no less than twenty-one times, the joint affection being rheumatic, neuropathic, gouty, or due to strained position; thirdly, to the fact that a difficulty in writing is not very infrequently hereditary, or

developed very early in life; and that, fourthly, any evidence of involvement of the nerve-centres is decidedly rare. Writer's cramp has been spoken of as a disease of "faulty co-ordination," and such, no doubt, is the case. Although we are not justified in assuming that there is a special co-ordinating centre for the act of writing. The existence of such a centre is improbable because, (1) in most instances of writer's cramp, there is evidence of peripheral change only; (2) if there be such a centre it must be created as it were by education; and the fact that it is scarcely more difficult to write with the toes than with the fingers is much against the probability of the existence of a writing centre. Then (3) this affection is never suddenly established as aphasic sometimes is; and (4) a purely peripheral lesion is sufficient to account for the symptoms. The author is still induced to call this affection a "fatigue disease." This fatigue may be the expression of hyperæmia or mild inflammation of a motor nerve, which may be caused by overwork, cold, rheumatism, injury, &c. Or it may occur from prolonged strain, especially as prolonged strain of certain muscles is inseparable from the act of writing. Lastly, Dr. Poore would class this disease among the neuralgias, a disease the phenomena of which are purely local, but which are due not only to conditions affecting the sensory area involved, but also to molecular change affecting any part of the sensory fibre, before or after its junction with the nerve centre.—Dr. BUZZARD, after complimenting Dr. Poore on the great value of his paper, remarked that the facts advanced by Dr. Poore coincided with his own observations. He did not think that writer's cramp could be regarded as a disease *sui generis*; and he noticed that the author of the paper had not alluded to lead poisoning as a cause of this affection. Dr. Buzzard had also seen cases associated with gout, and which were probably due to the existence of a gouty neuritis. Nor did he think that the peripheral theory of the disease had been thoroughly made out, for there was much to be said in favour of a centric cause. The fact that the affection commenced in the smaller muscles and gradually spread to other and larger muscles, and the fact that in a few cases if the right hand is no longer used, the left hand called into play would become affected, were arguments in favour of a central, rather than a peripheral, lesion. Dr. Buzzard's view of the causation of writer's cramp, was as follows: The frequent undue use (or even the ordinary use in persons of unstable nervous equilibrium) of certain muscles in performing a special act must cause a continued state of congestion of the centre controlling the movements of those muscles. Such a congestion might eventually lead to atrophy or want of nutrition in that particular portion of the nervous centre; and hence would ensue a certain amount of paresis and consequent alteration in the muscles over which that centre presides. This again would react upon the centres themselves; for, in proportion to the difficulty of muscular action, the greater would be the amount of nervous energy directed to the limb, and this continued overflow of nervous energy would cause more and more groups of muscles to be involved.—On the other hand, Dr. BROADBENT thought that Dr. Poore's paper afforded a solid basis for the view that writer's cramp was really a peripheral disease; and he had long thought that the periphery of the nervous system had been much neglected. He also perfectly agreed in the author's rejections of a special co-ordinating centre for the act of writing.—Dr. POORE then replied to some of the observations that had been made on his views of the disease, after which the Society adjourned.

SURGICAL SOCIETY OF IRELAND.

THE Fifth Meeting of the Session was held on Friday, February 1, 1878, Dr. ROBERT M'DONNELL, President, in the Chair.

The minutes of the previous meeting having been read by Mr. B. WILLS RICHARDSON, Hon. Sec., and confirmed,

Mr. H. TYRRELL made a communication to the Society on the subject of

EXCISION OF THE KNEE-JOINT.

In making the communication he did not desire that the question of the propriety of the operation of excision of the knee-joint—when it should be done, or in what cases it should be done—should be discussed, but he simply wished to deal with the mode of treatment after the operation had been performed. For some years his colleagues in the Mater Misericordiæ Hospital and himself had had considerable experience of the operation, and so far back as 1874 he published some cases of excision of the knee-joint which he had performed after Mr. Watson's method, and put up by means of the plaster-splint, and in which that treatment succeeded remarkably well. Since that time he thought they had been improving on the operation, rendering it more easy, and perhaps also more satisfactory in its results. The two casts which he exhibited were merely examples of what might be done by the operation as it occurred in one of the cases, and perhaps he might be allowed just to remark very cursorily upon them. One was a cast of a leg before the operation, in which was shown that remarkable deformity described as elongation of the condyle, and which rendered it perfectly impossible to straighten the leg by any manipulative procedure. The knee-joint was excised, and the patient recovered satisfactorily with the limb in the position shown by the other cast. Now, as he had already intimated, what he particularly wished to draw attention to was the putting up of the limb after the operation had been performed, and in doing so he would illustrate what he wished to bring under the notice of the Society by the aid of some of the splints and other appliances which had been lately used in the hospital. In his first cases—and he must say that he thought he had never had better success than in his first cases—he used Mr. Watson's scored splint. The success was all that could be desired; but afterwards they found some little difficulty in preserving the limb from excoriation, but perhaps it was rather tedious in being applied. The splints he now exhibited were of various sizes corresponding to the various limbs that had been excised, and they had all been in actual use with many others, which he did not think it necessary to exhibit to the Society. The success of the operation, if it was to be performed at all, depended upon the perfect immobility of the limb after the operation; and any variety of splint, or in fact, any splint that did not cause the limb to be perfectly immovable was, to his mind, very defective, and perhaps some of the mortality which sometimes succeeded the operation was due to that fact. Anyhow, this much was quite certain, that to the surgeon who performed the operation was caused a great deal of trouble in the after-treatment if he adopted the long splint, which he believed was brought into practice by Mr. Butcher, and many of the other appliances which were found in the text-books of surgery. In order to perform the operation according to the method which Mr. Watson brought into practice, and which was sufficiently explained in his pamphlet published so far back as 1867 (in which he gives a number of cases in which he performed the operation of excision of the knee-joint) it is necessary to put the limb up in a plaster apparatus. In 1874 he (Mr. Tyrrell) performed the operation three times and adopted Mr. Watson's procedure. Since that time, in the Mater Misericordiæ Hospital, they had given up Mr. Watson's plan. The merit of the splint which he now begged to lay before the Society was not his. It belonged to his colleague Mr. Hayes, and it consisted of two distinct portions—a thigh portion and a leg portion, which were united by means of an iron crank or splice. The members would observe that the two portions of this splint were not on the same plane, the leg portion of the plane being higher than the thigh portion, for the simple reason that they had found that the great difficulty to contend against was the protrusion of the femur. As the femur was difficult to keep down, if they brought up the tibia to the same height as the femur, there was no necessity to exercise pressure on the femur. The operation was really a very simple operation so far as the doing of it went. There could be no doubt, no matter what had been written by some, that the simplest way was the simple straight incision rather below the patella, and he wished to direct attention to that point. By making the simple transverse incision sufficiently wide to allow free drainage, and having removed the parts and divided the soft parts by means of the saw which he now exhibited (and which was nothing but an ordinary saw with a movable back) with the greatest possible ease any section that was necessary could be made, and he would quote Mr. Watson's pamphlet to show that that saw was preferable to any of the analogous contrivances which had been adopted from time to time. In fact, he (Mr. Tyrrell) did not believe that any peculiar variety of saw of very difficult construction was required. For all operations in the Mater Misericordiæ Hospital that saw (of which the specimen he exhibited was a small variety) was used, and any person

could, he thought, understand that once the saw entered and became fixed in the bone it was quite impossible to make anything but a straight section. As soon as the saw became perfectly fixed in the bone the strengthening part of it from the handle was detached, and then it ran through the bone with the greatest possible facility. As soon as the parts were removed then the limb was brought down, and when it became straight then the surgeon proceeded with the dressing. Now, in the case which was illustrated by the plaster-casts to which he had previously referred, a remarkable circumstance occurred which was very instructive. The patient, a young man, was permanently incapacitated from walking; he could not put his foot to the ground, and had been for many years in that predicament. When the operation had been performed, and when, as they thought, a sufficient section of the bone had been removed, they could by no means force the bones into position. They took off two slices of the femur, and then also found that it was impossible to place the bones in position. Having divided a number of ligaments and tendons, in fact, everything that was opposing reduction, as soon as these were divided the bone slipped into its place, but they found that an unfortunate accident had occurred. In making traction on the femur above the periosteum they found that the periosteum had become detached from the femur to the extent of about an inch. If they had removed that much from the femur the result would have been that they would have brought a very narrow portion of the femur in contact with a broad tibia, and there would not have been union. Having observed that the periosteum was not necessary for the life of the bone, they therefore took no notice of its having been pulled up, and proceeded with the dressing of the wound. The case went on satisfactorily, and a perfect cure resulted, as the casts now before the Society showed. After the joint was excised, the surgeon, all the while keeping the limb straight, of course, took a flannel bandage and rolled it round the limb from the toes upwards to the knee. Not only did he put one layer of flannel, but he put a second one, commencing to reverse the bandage for the second layer as soon as he came to the knee, about an inch below the wound. Having put that on, the surgeon left the bandage, as it were, loose, and proceeded to apply another double layer of the same flannel bandage from the groin downwards. By that means he had two layers on each portion of the limb, leaving about two inches of the knee exposed. Formerly, they were in the habit of using ordinary muslin and of rubbing into it a quantity of starch or plaster, but latterly he thought they had improved upon that. They had found that muslin was not sufficiently strong to make the traction necessary, and that it broke. For that reason they had discontinued its use. They now simply dusted a quantity of plaster into the flannel, which was exceedingly strong and would not break, even under very great traction. As soon as the parts were brought into perfect apposition, one of the splints he had already described, was applied, one portion of it along the thigh, and the other along the lower extremity; the quantity of padding applied to the lower extremity varying. However, a sufficient amount of padding must be placed along the lower extremity of the splint so that there would be no tendency for one portion of the limb to protrude beyond the other. They would observe that the quantity of padding they had to put into the tibial splint was very great indeed. The splint extended from about half the thigh, and embraced about three-quarters of the leg, more or less, as the case might be; but he did not pay much attention to that fact. The patient must now be thoroughly under the influence of ether, thoroughly relaxed, and if that was necessary at any part of the operation at all it was at that particular time. As soon as the patient was put into that condition one of the flannel rollers, properly plastered, was applied, commencing at the toes, as he had before stated, and taking care that the foot was at right angles to the leg, otherwise they might have some difficulty in geting the heel to the ground. The next point was, that they should put on the flannel bandages with the greatest possible force. One might think congestion of the limb might be produced by that; but such was not the case, for the plaster, when it dried, contracted outwards; if he might use the expression, it became loose. If they did not put it on with excessive force they would not have perfect immobility. The surgeon next got a piece of drainage-tube and laid it across inside the wound. Perhaps the most modern idea would be a piece of horse-hair. They had not tried it, because recently they had had no case. However, the drainage-tube answered remarkably well. The limb then lay in its support, and a piece of gutta-percha was applied across the knee; the plaster splint was strengthened either by an additional flannel roller, or some plaster was rubbed on by the hand. In reality, the operation was now over. In their first case they left the knee exposed, having put in a few sutures and a bit of tenax over it, but for the first week they found there was considerable swelling of the knee, and that in order to obviate this a simple device was resorted to; after the limb was got into position a piece of tenax and muslin was laid over the wound, and then a good lump of oakum, and one of the bandages on the leg was thrown round this, the drainage-tube coming out at the sides, so that it was perfectly free. That dressing was not removed for three, four, five, or six days, as the case might be. By means of the tube perfect drainage was allowed, and after three or four days it could be drawn out without giving the patient any pain, and on taking off the oakum it was generally found that the wound was healed; in fact, the whole difficulty of the case was over. He did not exaggerate in the least when he said that in several of the cases which had been done in the hospital the primary dressing was not removed until the patient was walking about. That was a literal fact, and perhaps some of the members had seen the cases to which he referred. The surgeon had no trouble in such cases, and in some instances that splint was positively the only dressing made at all, for it remained on for six weeks or two months, and when it became heavy to the patient it was taken off and some lighter material used. If there was a tendency to protrusion of the femur, in order to obviate that tendency, as slight as it might be, they had adopted latterly the plan of getting a piece of poro-plastic splint softened, and that was placed a little above the knee, and that entirely defended the femur from protrusion. Of the cases that had been treated by that means at the Mater Misericordiæ Hospital this much might be said: the surgeons had no trouble after the operation (which was in itself something), and none of the patients died from the operation. There were two or three cases in which amputation had to be resorted to, but they would be brought before the profession by-and-bye. The object of this communication was to deal with the method they had adopted in the after-treatment, which he believed to be very simple, very efficient, and in their hands had proved very successful. The only cutting instruments they used were the small scalpel, an ordinary blunt-scissors, and the saw with the movable back. He proposed to take another opportunity of dealing fully with the results of their experiments. They were not willing to rush into print prematurely after having had a few successful cases; they believed thoroughly in the efficiency of the operation, but it was only when a great number of cases under various circumstances had arisen that a person was in reality warranted in laying before the profession the results of his experiments and of his practice. He had omitted to mention how the limb was slung. All the members knew Salter's sling, but he and his colleagues found that that was not so good as the ordinary cradle. He now exhibited an ordinary cradle, and by means of a couple of rolls of bandage they were able to support the limb on three or four bands suspended from the top of the cradle. They did not use Salter's splints in the Mater Misericordiæ Hospital; in fact, they were not fond of complicated instruments or apparatus. They found that the limb slung in the manner described in an ordinary cradle, was far more efficient, and the limb could be lowered or elevated according to the necessities of the case. Sometimes the patients preferred being without it at all, and of course they might be gratified. To-day the limb had to be elevated, and to-morrow lowered. They could not tell why, but such was the case; and now the patient would have the limb at one angle, and now at another. The patient could, however, have the limb in any position he liked.

The PRESIDENT said he had seen Mr. Tyrrell's cases, and he saw the advantages of the mode of treating them that had been described. On the last two occasions, upon which he (the President) performed the operation he had adopted very nearly the plan that Mr. Tyrrell had detailed, and which he had with a slight modification recommended before. The point in Mr. Tyrrell's communication that night had struck him, and he would suppose from the way he mentioned that the periosteum was drawn up from the bone, that he thought it was rather an advantage, at all events, that it would do no harm. He (the President) did not think they could conclude that at all from the case he had mentioned. Of course, the

periosteum was laid down again at once with the bone, and thus the most important thing which injured the periosteum would not have occurr d. The thing which injured the periosteum most, was the separating it from the soft parts. If the periosteum retained its connection with the soft parts, and was laid down again with tolerable promptitude on the bone, then the chances were that no bad consequences would follow, as he presumed, was the result in the case Mr. Tyrrell had mentioned.

Mr. O'GRADY said there was one circumstance, under which the plaster of paris bandage might prove a source of embarrassment. In the case of the last knee he excised, he used Esmarch's bandage, and as happened to him in two or three cases he had reactionary hæmorrhage, he did not mean secondary hæmorrhage. In the last knee he ex ised, he had serious reactionary hæmorrhage. He followed Mr. Tyrrell's plan as faithfully as he could, and he (Mr. O'Grady), certainly, experienced a good deal of difficulty in opening the plaster of paris bandage, and taking down the knee, as it became necessary to do three or four hours after the operation. The hæmorrhage was not due to any vessel escaping the ligature. The tibia had been extensively diseased, and a large hole had to be gouged out of the head of the tibia. He put the limb up, as he thought, in a satisfactory way. However, hæmorrhage came on, and in arresting it, a great deal of trouble occurred in opening the plaster of paris bandage, for he had put it up very firmly with the view of securing the perfect steadiness of the limb which Mr. Tyrrell had called attention to. In treating for the hæmorrhage afterwards, he found that the application put into the hollow of the bone had failed to arrest the bleeding, so he put pledgets of carbolised catgut into every part of the cavity to the fullest extent, and compressed the two bones rigidly together, and that had the effect of arresting the hæmorrhage. The case was subsequently treated in the long Butcher's splint, and made a capital recovery in about two months or ten weeks, the girl being able to walk about on the foot. If we used Esmarch's bandage in the case of secondary hæmorrhage, it might be a matter of great embarrasment to open the plaster of paris bandage.

Mr. TYRRELL said there was but little to which he had to to reply. All of his operations were not done with Esmarch's bandage, because some of them were done before they knew anything about that bandage, but since that mode of operation had come into use, he had used it in every case. In none of them did he experience the difficulty that Mr. O'Grady complained of. Of course it was quite possible that such a thing might occur, but still he did not think there ought to have been very much difficulty. The patient should simply be put under the influence of ether, and by the aid of a proper pair of cutting pliers, the bandage could be taken off with great facility. The way in a great measure to prevent hæmorrhage, was not to be in a hurry, the apparatus should not be put on until the hæmorrhage was stopped. With regard to what the President had said, it certainly was not a pleasing thing to see a dragging up of the periosteum, leaving the bone bare for nearly an inch. They could not remove any more of it, because if they did, they would have too small a surface. That mishap was looked upon as a very unfavourable circumstance. In their case, they immediately drew it back with gentleness, and did the best they could. Happily the case turned out very well.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
AND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER X AND LAST—HISTORICAL AND BIBLIOGRAPHICAL.

The Geographical Distribution of Rabies.

IN an address, delivered at the Munich meeting of the German Association of Naturalists and Physicians, 1877, Virchow (1) said: "That medical men were the patriarchs of science, inasmuch as we have the dogmatic current at its longest, and medicine was the only science which has a continuous history of nearly 3,000 years."

(1) "On the Freedom of Science in the Modern State."

The evidence on rabies, illustrates both the antiquity o medicine, and the antiquity of our knowledge as to its existence, for it is veritably lost in the mists of time. We have the assertion of Plutarch that it was known in the days of the Asclepiadæ, we have the mythological legend, of the fate of Actæon, (2) and we have dimly floating traditions that it was known at a more remote period to the Egyptians.

We may divide, for bibliographical purposes, its history into different epochs, commencing with—

The Evidence and Writers before Christ.

Whether Homer was acquainted with the disease is a subject upon which commentators disagree. Various dates are assigned to his poems, as from 962 to 915 B.C., whilst Wolf has fixed their collection and arrangement by Peisistratus at 550 B.C.

The Greek term for rabies we have mentioned—Lyssa. Homer (3), in his "Iliad," compares Hector to a mad dog, a term applied by Teucer; whilst Ulysses, speaking of him to Achilles, says (4)—

"So with a furious *Lyssa* was he stung."

The word occurs in other places.

Moseley (5) does not believe that Homer referred to this disease, and observes that the epithets given to Hector, which have puzzled and misled conjecturers, mean nothing more than that his violence resembled insanity, and his fury rendered him like an enraged dog.

Hippocrates (6) is supposed, by some, to refer to the disease from the following passage—

"Phrenitici parum bibunt, ex levibus strepitibus facile irritantur, tremuli sunt aut convulsionibus tentantur." He does not mention it by name, so that it is a matter of inference from his general knowledge, and from the fact that it was known about his time, that he must have been acquainted with it. He is supposed to have been a contemporary with Socrates, and Zenophon, (7) another contemporary, has left us some lines in which the word lyssa has been introduced, it occurs in a speech addressed to his soldiers. Hippocrates' (8) birth is fixed, on the authority of Soranus, in the year 460 B.C.

Aristotle (9) (B. 384 B.C. D. 322 B.C.), has left a description, clearly proving that canine madness was known in his time, for he says: "Dogs are subject to three diseases—rabies, angina, and podagra; rabies causes madness in dogs, and all animals they bite have the rabies, excepting man."

The ancient Jewish oral, or unwritten law, is compiled in the Talmud, a work reputed to have been carried on from 536 B.C. to 220 B.C., and it is said that rabies was known at that period, as it is mentioned in the records we possess of these writings.

Democritus who lived about 400 B.C., and some of whose works have come down to us, has also the credit of having recognised the disease, whether his writings are apocryphal or not, we are told (10) that he attributed the seat of the disease to the nervous system.

Virgil (B.C. 70, D. 19 B.C.), though not a physician, according to Moseley, in his descriptions, comes nearer the mark than any physician who had written expressly on the subject.

He classes canine madness among the distempers of sheep and cattle, and as brought on by a pestilential state of the atmosphere.

(2) "Inscius Actæon vidit sine vesto Dianam
Præda fuit canibus nec minus ille suis."
—OVID Tristia.

(3) Homer, Iliad viii., 299. Iliad ix., 239. Iliad xiii., 53. Iliad xiii., 542. In reference to Homer and the word Lyssa, see Liddel and Scott's admirable Lexicon, in which, under the word λυσσα will be found a set of references, which bear on the question. The passage which they mention from Pliny tending strongly to confirm the view of Homer's acquaintance with canine madness.

(10) Holland and Shinkwin's Lectures.

In the 3rd book of the Georgics, line 496, he says—

"Hinc canibus blandis rabies venit."

As an instance of recovery, reported to have been cured by bathing, we may mention the case of Euripides, one of the Greek tragic poets, the received date of whose birth is fixed in the year 480 B.C., and whose death is assigned to the year 406 B.C. Many other references may be found in other writers, but we have selected only a few; they afford ample and satisfactory proof of the early period at which rabies was recognised both in man and animals.

The Evidence of Writers from the Second to the Tenth Century.

As a connecting link between the two periods, we commence with Celsus, the so-called Roman Hippocrates, who flourished under the Augustan era which began 27 B.C., and ended 14 A.D. The writings of Celsus have furnished inexhaustible materials for subsequent writers, and his works on medicine are familiar to nearly every modern student and physician. His evidence is very valuable, for he tells us the origin of the name which has come down to us through so many centuries.

"The Greeks," he says (11) "call it *ὑδροφοβια*, a most wretched disease, in which the sick person is tormented at the same time with thirst and the fear of water, and in which there is but little hope," This sagacious and celebrated physician fully recognised both the disease and its dangers, and though many of his views are irrational, there is a substratum of truth in them. He was of opinion that the bites of all animals were dangerous from the presence of some venom: "Autem omnis morsus habet fere quoddam virus." In his precautions, he has forestalled many of the remedies of after ages, for he recommends suction, and refers as a proof of the innocency of the operation to the family of Psylli, who with the Marii enjoyed the special privilege of extracting the poison by suction with the mouth. In sucking the wound it appears to have been recognised that it was most essential for the safety of the operator that no sores or abrasions should be on his lips or in his mouth. (12) In the following description we have an enumeration of his other remedial measures. He tells us, "if the wound be violent the cupping instrument is to be applied, and if very slight a plaster is to be immediately put on, and particularly that of Diogenes . . . Afterwards, if the part is neither nervy nor muscular, the wound is to be cauterised; if it cannot be burnt it is not unfit for blood-letting. Then those applications suitable for other wounds are to be put over the burnt wound; but if not burnt, then those medicines which violently corrode; after which the ulcer will be healed in the usual way." (13)

We have mentioned in another chapter his views on the efficacy of bathing.

From the Greek name of this disease there can be no doubt, the Roman physicians derived most of their knowledge from their Greek brethren, and amongst the writers of the first century we must estimate Pedanius Dioscorides, the author of a celebrated work on materia medica.

Dioscorides (14) mentions that a man named Themison had the disease, and recovered. His treatment was somewhat similar to that of Celsus, but he advised extirpation by the knife, scarification of the parts above the wound, and the use of a drain to prevent the virus passing into the system. He also ordered cupping, and in desperate cases burning, believing fire before all other things to be the most efficacious in destroying the virus.

Gratius Faliscus, a poet and contemporary of Ovid, mentions rabies as a disease of dogs in his work entitled the "Cynegeticon," and Ovid, (15) (18 A.D.), has alluded to rabies and its fatality, along with gout, in the following lines:—

"Tollere nodosum nescit medecina podagram nec *formidatis auxiliatur aquis.*"

Pliny (16) (B. A.D. 22, D. 79 A.D.), the indefatigable observer and collector of facts, no matter of what nature or importance, has left us some amusing descriptions of the various remedies for the disease in his voluminous work on natural history, and the curious will find in the thirty-seven books of his "Historia Mundi" many interesting references to the malady—a veritable *mélange* of accurate observation mingled with superstition and absurdities.

(11) Celsus, lib. v. c. 27.
(12) De Medicina, book v. c. 27.
(13) Celsus, lib. v. c. 21.
(14) Dioscorides, lib. ii. c. 12.
(15) Ovidii, ep. ex ponto, lib. i.

We may also mention the names of Columella (17), who informs us of a superstition which has been practised even in our own day. He tells us it was believed amongst the shepherds that if on the fourtieth day after the birth of a pup, the last bone of the tail is bitten off, the tail will not grow, and the dog will be secured from rabies.

Scribonius Largus, (18) a Roman physician in the time of Claudius (41 A.D. to 54 A.D.) briefly notices the disease in man, and asserts that no person was ever cured of it.

Cælius Aurelianus has been considered one of the best of the ancient authorities on this disease; the period when he flourished is uncertain.

Some writers place him as early as the first century of the Christian era, whilst others assert that he was at least a century later. (19) He has evidently borrowed from older writers, as Eudemius, Soranus, and others. He has left us a very accurate description, to which we have previously alluded. He refers to the possibility of hydrophobia arising as a symptom in other diseases, for he says:—

"Est præterea possibile, sine manifesta causa, hanc passionem corporibus inasci cum talis fuerit strictios, ponte generata qualis a veneno." (20)

Aurelianus adopts a more hopeful tone than many of our modern physicians, for he tells us that sometimes patients suffering from this disease are cured:

"Quomodo curandi sunt hydrophobi."

He has detailed the measures adopted by his predecessors, and in many respects they favourably compare with the practice of the year 1800.

Galen, (21) (B. 130, D. 200 A.D.), the author of so many medical treatises, has left us a number of antidotes collected from the recipes of the Greek physicians, from which it would appear that rabies was well known, and a prevalent disease amongst them. His antidotes are of the most varied nature, and are principally interesting as illustrating the practice of his time. We also thus learn the names of a number of the physicians of his time, as Æschrion, Zopyrus, Cratippus, Hiras, Belchionius, Zeno Laodicei, Menippus, and Menelaus.

Galen exercised a considerable influence on succeeding writers, for his opinions were received by the ancient physicians as sacred oracles, and it would have been deemed a crime not inferior to heresy or treason for his successors to have opposed such authority. Lipscomb, in alluding to the influence of Galen, remarks:—

That the respect and veneration which were attached to the name and rank of Galen, shut the doors of improvement on many succeeding generations, who accordingly, never ventured to examine, still less to contradict any of his opinions.

In the third century we have evidence of the existence of rabies furnished by Claudius Ælianus of Præneste, Claudius Galenus of Pergamus, and Olympius Nemesianus, a Carthagenian poet; whilst in the fourth century, Oribasius, of Pergamus, physician to Julian the Apostate, has described it, and alludes to its being generally fatal.

"Ex is vero qui a cane rabioso morso fuissent, servatum esse neminem." This opinion he derived from Apollonius (23) of Pergamus, who also said that persons having this malady from other causes are sometimes cured.

Aëtius probably lived in the fifth century, though historians are not agreed about the exact date. (24) He was a native of Amida, and studied at the famous school of Alexandria. He has often been confounded with Aëtius, so-called the atheist, who lived at the time of Julian the Apostate. His description of the disease in dogs, is considered the most accurate of any of the ancient writers.

Case CLII.—Jane Filmer, domestic servant, æt. 36, residing with a family on the Marine Parade, Dover, bitten by a strange dog whilst on her way to church.

Result and Time of Attack.—Nine months after. Fatal, second day.

Remarks.—She mistook the dog for her master's. She

called and stroked it with the object of relieving it of a bramble which had clung to its back, when it turned and bit her between the thumb and forefinger. After her return from church the wound was cauterised, but the symptoms of hydrophobia manifested themselves on Sunday, Dec. 30th, 1877, and, notwithstanding that everything was done which the highest medical skill could suggest, she died after the most horrible sufferings at half-past ten o'clock on Monday night. A verdict of "Accidental death" was returned.

CASE CLIII.—W. Hulme, æt. 5.

Result and Time of Attack.—Eight weeks after. Fatal, third day.

Remarks.—The child was going to school when a small spaniel dog ran at him, knocked him down, and bit him on the lower lip; and also bit a little girl named Albiston on the hand. The wound was cauterised, and the boy went to school as usual. On Saturday night, 29th Dec., 1877, when about to be washed, he vomited, and seemed exceedingly terrified at the sight of the water. During the night he sprang up in bed wildly. He, however, went to school on Sunday morning. Great efforts were made to induce him to partake of water and eatables; he appeared anxious to do so but was frightened. The characteristic symptoms of the disease increased in severity, and he died on Wednesday, January 2nd, 1878. A verdict of "Died from hydrophobia" was returned.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 20, 1878.

HEART DISEASE IN THE ARMY.

THERE are few who will not be interested in anything that concerns the health of those soldiers upon whose good physique, discipline, and bravery, we chiefly depend for the defence of our country and the protection of "British interests." Unfortunately, however, the health of our troops, whether engaged in active service or not, has been long interfered with by various practices and habits, and by various Regulations of the Service that have continued in operation in spite of all representations as to their injurious consequences.

Mr. Myers has recently drawn attention to the causes, which, in his opinion, are at work in the production of heart disease in the army. He points out the much greater prevalence of heart disease among soldiers than among civilians, and after making due allowance for the operation of the ordinary causes of this class of disease, he comes to the conclusion that some other cause must be at work to account for the fact above mentioned, and that that cause consists in the mechanical obstruction to the circulation which is occasioned by the tightly-fitting clothing and accoutrements of the men. Surgeon F. Arthur Davy, M.D., in an able paper contributed to the *Army Medical Report* for 1876, endorses the opinion of Mr. Myers, and says that it is much to be regretted that the soldiers' dress does not allow that complete freedom from constriction which, when work is expected of him, he ought to enjoy. But Dr. Davy points out another powerful influence in the causation of heart disease in the army, namely, the manner in which the early training of the recruit is conducted.

In order to improve the physique of the recruit, he is made to stand bolt-upright, his head well back, and his chest dilated to the fullest inspiration, is kept as much distorted as possible. Under these circumstances there is great elevation of the ribs, great depression of the diaphragm, and the sternum is thrown forward. The stethoscope reveals an abnormal character of the heart's impulse, and shows that the distended condition of the lungs has not given place to a properly performed expiration, that in fact the expiratory act is to a great extent in abeyance. Accordingly, the interdependent functions of the heart and lungs are seriously interfered with; and not only, observes Dr. Davy, will the elastic recoil of the lungs and of the chest wall be, by repetition of this training, gradually diminished in power, but the blood, as the man stands, undergoes a deficient aëration. For, owing to this imperfection of the expiratory act, the air in the lungs, charged with carbonic acid, is not expelled to the usual extent, to be replaced by new air from without. In virtue of certain well-known physiological facts, the due performance of expiration is of the last importance when active exercise is taken. The drill of the soldier is not active exercise, and that is the only reason why the position is tolerable at all. In the artificial condition, moreover, under which the recruit is placed, the abdominal muscles are not only weakened by the over-stretching to which they are subjected, but their action is antagonised by the diaphragm being kept depressed. The alterations therefore, of the physiological conditions under which the expiratory act is performed in health are greatly altered, and this alteration cannot take place with impunity, as pathological states commence when physiological conditions are departed from. Independently of heart disease, Dr. Davy is convinced that vesicular emphysema, to some extent, occurs in nearly all the men, during the period of training, from the continued and excessive distension of the air vesicles. The drill sergeant may soon increase the measurement of the recruit's chest, but this is done at the expense of its mobility, at the expense of its vital capacity, so that the recruit is thereby more or less unfitted for active service. The truth of this remark is obvious, and is further corroborated by the observation of Mr. Hutchinson with the

spirometer, for he found the vital capacity of the lungs was not so much in proportion to the size of the chest as to the mobility of the walls of the chest. Hence with regard to the soldier, the erroneous opinion prevails that the man with the dilated chest is a fine, able fellow, when, as Dr. Davy remarks, he might not be able to blow out a candle at a distance of two and a-half feet.

On examining men who have suffered from the effects of this drill, it is found that in the distended chest the cardiac impulse is lower down and nearer to the middle line than it ought to be; its area appears to be increased; it can even be seen to be abrupt and jerky, and in many instances there is marked epigastric pulsation. On palpation, the cardiac systole is found to be more powerful than natural, although the man is only standing. The condition of the walls and floor of the chest remain as above described. The heart contracts about 110 times in the minute, the rhythms being irregular both in time and force, and the respirations are shallow and frequent, being often 40 in the minute. Consequently, although tight clothing, &c., is a cause of obstructed circulation from without. the conditions now under consideration are a more powerful cause of obstruction from within, for inasmuch as the expiratory movement assists the heart in propelling the blood in the arteries; it follows that any obstruction to this movement must disturb the balance which exists in health between the pulmonary and the systemic circulation. Dyspnœa is sometimes great, especially if the recruit is required to double, and the right ventricle is much embarrassed. Dilatation or hypertrophy, or both, is often observed; and the dyspnœa frequently complained of is perhaps one reason which induced Mr. Myers to remark upon the "severity" of the drill, and the "exhaustion" he has seen produced by it.

Space will not allow us to enter more deeply into the subject, but we think Dr. Davy has shown that the mode of dealing with the recruit's chest is artificial and injurious; that the causes of the visible embarrassment of his heart, under training, have not, in his interest, been sufficiently considered; that it has not been suspected that this embarrassment—continued as it is for many months for three or four hours daily—may, and does, induce organic disease; in a word, that the recruit is the victim of the drill sergeant's ignorance, and of the prejudices and conservatism of the army authorities. No sanatarian would deny that during the period of drilling the action of the chest and lungs should be perfectly automatic. The chest movements should vary in extent in accordance with the amount of blood sent into the lungs, which amount is mostly regulated by that of the muscular action, and the effect which this action has upon the circulation through the veins; but these movements should not be impeded by attention being in any way directed to them.

We certainly hope that the very instructive observations of Mr. Myers and Dr. Davy will induce the authorities in the army to make some alteration, both in the more objectionable methods of clothing the men, and in the present system of drilling. Many months ago, in an article on the Physical Education of the Army, we drew attention to the comparative neglect into which this subject had been allowed to fall. There is nothing in the present system of drilling to improve either the strength, or agility, or power of endurance, of the soldier. It was not in this way that the old Roman soldier was taught how to endure all the hardships of war, and the Roman legions to obtain the mastery of the world. There was no standing "bolt-upright," keeping their chests in an artificial state of distension, and assuming an appearance of strength and a physique which they did not possess. "Military exercises," observes Gibbon, "were the important and unremitted object of their discipline. The recruits and soldiers were constantly trained both in the morning and in the evening, and care was taken that the arms destined for this imitation of war should be of double the weight which was required in real action. Their exercises comprehended whatever could add strength to the body, activity to the limbs, or grace to the motions. They were diligently instructed to march, to run, to leap, to swim, to carry heavy burdens, &c." We might certainly take a lesson from them, and replace some of that formal, artificial "red tape," and, as we have seen, unhealthy drill of the present day, by some of those practices which brought the Roman soldiery to such a state of physical perfection. We might then have less heart disease among our troops, and more capability on their part of making, without being exhausted, long and difficult marches; and of maintaining in good health under whatever circumstances they may be placed.

THE LEGAL INCORPORATION OF DENTAL SURGERY AS A DISTINCT SPECIALITY.

THE Bill of Sir John Lubbock, which is now before the House of Commons, is deserving of careful consideration, not alone from its immediate relation to surgery and surgeons, but from the principle which it involves. We have the measure before us, but it will suffice for the information of our readers that we briefly note its provisions. Its principal clauses, all important phrases of which we quote verbatim, are as follow:—

1. A person shall not, under a penalty of £20, be entitled to take or use the name or title of "dentist" (either alone or in combination with the word "surgeon" or with any other word or words), "dental surgeon," or "dental practitioner," or any name, title, addition, or description implying that he is registered under this Act, or that he is a person specially qualified to practise dentistry, unless he is regestered under this Act."

2. He shall not be entitled to recover fees unless registered.

3. Any person who—

(*a*) Is a licentiate in dental surgery or dentistry of any college of surgeons in the Kingdom, or of the Faculty of Glasgow; or,

(*b*) Is at the passing of this Act *bona fide* engaged in the practice of dentistry, either separately or in conjunction with the practice of medicine or surgery,

Shall be entitled to be registered under this Act. No further restriction whatever is imposed.

4. A fee of £2 is payable as registration of existing dentists, £5 for those registering after January 1st, 1879.

5. It shall be lawful for the R.C.S.Ed., and the F.P.S.G., and the R.C.S.I., to hold examinations for the purpose of testing the fitness of persons to practise as dentists who may be desirous of being so examined, and to grant certificates of such fitness; and any person who obtains such a certificate from any of those colleges shall be a licentiate in dental surgery or dentistry of such college, and his name shall be entered on a list of such licentiates to be kept by such college or body.

Each of the said colleges or bodies shall admit to these examinations any person desirous of being examined who has attained the age of twenty-one years, and has complied with the regulations in force (if any) as to education of such college or body.

6. The colleges shall appoint examining boards to consist of at least six members, one half of whom at least shall be persons registered under this Act, and such registration shall be deemed the only qualification necessary for the membership of such board.

7. Examination fees to be fixed by each body.

8. These examinations and licenses shall be subject to the approval of the Privy Council, exactly as medical qualifications now are.

The other provisions of the Bill are mere details exactly similar to those contained in the Medical Act of 1858.

Taking this Bill as a whole, and looking back upon an experience of the working of the Medical Act, a more unsatisfactory, strife-begetting, dangerous measure, it would be difficult to frame.

In the first place, it perpetuates in the worst form that diploma-selling competition amongst Colleges which has proved the opprobrium and bane of the medical profession. While it confers upon three Colleges the right to make dental licentiates, it not only makes no attempt whatever to ensure that uniformity which medico-educationalists are now striving to obtain, but it offers to each licensing body a direct temptation to undersell the other in the money and education value of their dental diplomas. The Colleges are bound to admit to the profession of dentist, every one who has achieved 21 years of age, and "has complied with the regulations in force (if any) as to the education," and when they have admitted him, they may examine him as they please, charge him what they please, and license him as they please, and are subject to no restriction whatever, saving the chimerical supervision of the Privy Council and the financial necessities of the diploma traffic. One college may insist on its dental licentiate being also a surgeon, the next may accept the druggist in the next street if it pleases; and if we may judge by experience, a competition for the patronage of the counter-prescribing chemists is to be expected with certainty if ever the Bill becomes law.

The worst part of the Bill is undoubtedly the clause (5) which defines what a legally-qualified dentist is to be. We know what the dental surgeons (by examination) of the future may be, but we have not yet learned who are to constitute the legally-recognised dentists of our own day. Under the fifth section every one who "is at the passing of this Act *bona fide* engaged in the practice of dentistry either separately or in conjunction with the practice of medicine or surgery, is *ipso facto* entitled to registration. Do our readers appreciate the meaning of this proviso? Do they realise the fact that every advertising trader in false teeth, every proprietor of a door-post case of clock-work jaws, every mechanist who has learned to work in vulcanised India-rubber, is to be authorised to practice as a dental surgeon, or dentist, and assume whatever title of the same significance seems to him best? His sole and total qualification is to be a declaration *made by himself, concerning himself,* and to the effect, simply, that he is in practice at the date of passing of the Act; and on the authority of this patent of nobility, he is to be enrolled in a register, kept and published by the General Medical Council, and to be entitled to appear in Court, sue for fees, prosecute what he is pleased to call an unqualified practitioner, and in all respects enjoy the privileges of medical men, saving the use of strictly medical titles. We trust that the profession will not fail to take energetic action towards the defeat of Sir John Lubbock's most objectionable measure.

Notes on Current Topics.

Treatment of Infantile Convulsions by Hypodermic Injection of Ether.

We must not be surprised at anything we hear respecting the use of hypodermic injection, considering the rage there is just now for administering medicine in this fashion. In a recent number of *La Presse Médicale*, Dr. Gellé cites a case in which the above treatment was successful, and in which the method adopted was called for by the urgency of the symptom, and the impossibility of administering any remedies by the natural channel. Besides, the exact quantity of the medicine used could be estimated, which cannot be done when inhalation of chloroform or ether are employed. The infant was only seven months old, and, owing to improper feeding and the irritation of dentition, was suffering from continual vomiting and purging pain in the bowels, fever and fits of general convulsion alternating with a comatose condition. The chief indications were to arrest the vomiting and convulsions, then to bring on a crisis by sweatings, and lastly, to watch for the approach of a threatened attack of pneumonia. Ten drops of sulphuric ether were injected hypodermically into each leg of the child. The insertion of the instrument did not arouse the little patient. The convulsions ceased and did not return after the injection of the ether, the vomiting also ceased, and a period of repose was succeeded by a natural sleep.

The subcutaneous introduction of volatile anæsthetics is now frequently resorted to in France, and the object of Dr. Gellé in publishing the above case is to give his experience of this method of treating some forms of infantile convulsions.

Iodide of Potassium in the Treatment of Asthma.

At a recent sitting of the Academy of Medicine, Paris, M. G. Sée read a paper on the results he obtained by this method in 24 cases, including 4 children, 16 adults, and 4 old persons. "These results," he says, "have been very remarkable, both in respect of the cure of the patients, and of the rapid disappearance of the accidents which characterise this affection." M. Germain Sée, who has had chiefly under his observation those cases of asthma which are contracted in the course of whooping-cough, or of bronchitis, has been able, by the means he employed, to ward off the attacks even when they were

on the point of manifesting themselves. The iodide of potassium should be combined with a certain quantity of opium (5 or 6 centigrammes) or of chloral, to prevent the occurrence of iodism. The two formulæ employed by M. G. Sée are as follows — 1. Iodide of potassium 1 gr. 50 centigrammes, and extract of thebaia, 05 centigrammes. 2. Iodide of potassium as above, and chloral 1 gr. The dose of the iodide may be gradually increased. In asthma not complicated with emphysema, the respiration should become free two hours after the administration of the medicine, the natural respiratory murmur is again heard, and the dry and sibilant *râles* become mucoid or moist. M. Sée attributes this result to the effect of the iodide upon the nervous system. Another remedy, the *iodide of ethyl*, is more prompt and efficacious than the iodide of potassium. This volatile and very absorbable substance combines the action of iodine and ethyl.

Analysis of Water.

In the appendix to the Army Medical Report for 1876 Dr. F. de Chaumont has some interesting remarks on the analysis of water as conducted in the Army and at Netley with regard to the determination of organic impurities; they adhere at Netley to the ammonia process of Wanklyn and Chapman. In the new edition of Wanklyn's book the use of the sodium solution in distilling for the free ammonia is practically discarded. At Netley they always combine a determination of the oxidisable matter by the permanganate with the ammonia processes, and by that means get information of more value than from either process alone. With respect to the mineral constituents Mohr's new process for the determination of carbonates is a very elegant one. It is founded on the fact that the presence of carbonate imparts a certain alkalinity to the water which is readily detected by the use of cochineal. The introduction of this substance instead of litmus is a great advantage. It is much more sensitive, and gives much sharper indications. Its natural colour is a carmine red, which is at once changed by acids to a yellow or reddish-yellow. The change is sharp and sudden, with no return of colour, as is the case with litmus. The solution is prepared by bruising a little of the commercial cochineal in water which has been gently heated, adding a little alcohol, and filtering. For the process a standard solution of sulphuric acid is prepared by dissolving 4·9 grammes (by weight) of pure H_2SO_4 and diluting to 1 litre; 2 ccs. of this are equal to 10 milligrammes of carbonate of lime. If 700 ccs. of water be operated on, 2 ccs. of standard solution used will represent 1 grain of carbonate of lime per gallon. The process is simple: 700 ccs. of the water are taken, and a few drops of cochineal solution added (*N.B.* the colour should not be too deep), the solution of acid is dropped in until the carmine red is changed yellow; read off the ccs. used and divide by 2, the result is grains of carbonate of lime per gallon. With regard to search for poisonous metals, the qualitative test is really all that is necessary for hygienic purposes. Lead and copper can be recognised in very small quantities by means of a solution of ammonium sulphide, which will produce a dark coloration of sulphide of the metal: if the water be then acidulated with hydrochloric acid without the dark colour disappearing we may be certain that lead or copper is present. Should the acid clear up the water, the sulphide has been iron only.

The late Dr. Handsel Griffiths.

A committee has been formed for the purpose of collecting a fund for the family of the late Dr. Handsel Griffiths, librarian of the Royal College of Surgeons. Everyone who has been in the habit of using the library of the College of Surgeons knows how anxious Dr. Griffiths always was to oblige those who entered the rooms; and now that he is gone we feel assured that his unfailing courtesy and cheerful readiness to meet the wishes of every Fellow, Licentiate, and Student, who wished to consult the books under his charge, will not be forgotten. His civility and modesty had endeared him to all, and his talents and wonderful industry seemed likely very soon to place him in a position of independence, but overwork had thoroughly prostrated him when he was attacked with fever, and his untimely death has left his family in great need of aid. The Council of the College of Surgeons have voted £100 to his widow, and the object of the committee is to raise a sum which, added to that, will enable her to furnish a house and make a struggle for the maintenance of herself and her little ones.

By the kind permission of Dr. Robert M'Donnell, President of the College of Surgeons, an account for the "Griffiths' Fund" has been opened in the Ulster Bank, Lower Baggot Street, in the joint names of himself and Dr. James Little. Subscriptions may be lodged to the credit of this account, or sent to Dr. Little, 24 Lower Baggot Street, by whom they will be formally acknowledged.

Mortality at Paris.

During the week ending Jan. 24, 1878, there were 1,051 deaths from the following causes:—Typhoid fever 16, measles 22, small-pox 2, croup 24, diphtheria 31, bronchitis 60, pneumonia 90, choleraic diarrhœa of infants 5, puerperal complaints 4, erysipelas 6, other acute affections 260, chronic disease 457 (of which 164 were pulmonary phthisis), surgical complaints 49, and accidental causes 25.

A Unique Plant.

A plant with a strange history is figured in the last issue of Hooker's "Icones Plantarum." It is the *Lampra volcanica* (Benth.). Of this curious plant, says Bentham, only a single specimen is known, which was gathered by Hartwig in the crater of the Volcan de Agua, in Central America, at an elevation of 14,000 feet, in August, 1840.

Operations under the Red Cross.

Dr. Manoury has furnished *Le Progrès Medical* with an account of the movements of No. 5 Ambulance of the Red Cross Society during the present war in the East, and as it has peculiar interest at the present time, we give our readers a translation of the following table of major operations from Oct. 20 to Nov. 8, 1877:—

Name.	Nature of Wound.	Dates before Admission.	Operation.	Date	Name of Surgeon.	Observations.
Mehemet Ali ...	Fracture of right humerus by ball	—	Circular amputation of arm	Oct. 20	Macpherson	Death from secondary hæmorrhage
Mehemet Osman	Wound from ball of left coxo-femoral articulation	6 weeks	Abstraction of ball and resection of head of femur	,, 21	Rudduck	Pneumonia, death
Alil Beskiste ...	Comminuted fracture of left leg	2 months	Amputation of leg at upper third	,, 21	Manoury	Under treatment
Mehemet Ahmet	Wound of left elbow by splinter of shell	2 months	Resection	,, 21	Mackellar	Under treatment
Ahmet Ibrahim...	Fracture of right humerus by ball	6 weeks	Amputation of arm	,, 21	Mackellar	Under treatment, cicatrisation almost complete
Alil Mustapha ...	Comminuted fracture of femur by ball	2 months	Amputation of thigh at upper third	,, 22	Rudduck	Pyæmia, death
Ahmet Ibrahim...	Fracture of left leg by ball	—	Circular amputation of leg	,, 22	Mackellar	Gangrene of stump, amputation of thigh by Macpherson, Nov. 5, death
Ahmet Ali ...	Wound of left elbow by splinter of a shell	—	Resection	,, 22	Mackellar	Under treatment
Ismael Ali ...	Wound of right foot by splinter of a shell	6 weeks	Amputation of leg at lower third	,, 22	Pinckerton	Under treatment
Ismael Ahmet ...	Comminuted fracture of left tibia by shell	—	Flap amputation of leg	,, 29	Rudduck	Death
Selim Mehemet Ali	Comminuted fracture of bones of right leg by shell	—	Flap amputation	,, 23	Kirkpatrick	Dysentery, death
Shaban Satonimus	Fracture of the radius, with necrosis of the humerus	6 weeks	Amputation of the arm	,, 23	Vachell	Under treatment
Hassan Ali ...	Penetrating wound of the right knee, with ball in one of the condyles of the femur	—	Resection	,, 25	Rudduck	Pyæmia, death
Marzur Ali ...	Mangling of the right hand by shell	1 month	Amputation of the forearm	,, 26	Rudduck	Cicatrisation almost complete
Hassan Ismail ...	Fracture of the bones of left leg by shell	—	Amputation of leg at lower third	,, 26	Rudduck	Death
Hassan Ali ...	Complicated fracture of bones of forearm by shell	—	Amputation of arm	,, 27	Rudduck	Death
Kerim Mehemet	Complicated fracture of right leg	2 months	Amputation of thigh at lower third	Nov. 1	Kirkpatrick	Under treatment
Mehemet Ali ...	Fracture of femur	—	Amputation of thigh	,, 2	Macpherson	Death
Annis Mahmed...	Fracture of the right leg	4 months	Amputation of thigh	,, 3	Kirkpatrick	Under treatment

We regret we have not space at present to transcribe Dr. Manoury's report *in extenso*, but we must quote one sentence. Dr. Manoury observes: "From what I have said, it will be seen under what deplorable conditions the operations have been performed; almost all ought to have been performed earlier; many refused to have any operative procedure at first, and when some days after they contained, their condition was unfavourable." Hence, we need not wonder at 10 deaths out of 19 operations.

Conviction of a Quack Doctor.

The defendant in this case was the notorious Dr. Hamilton, formerly keeper of a so-called anatomical museum in Oxford Street. The present action took place in the Common Pleas Division of the High Court of Justice, before Mr. Justice Lindley, without a jury, the Medical Alliance Association being the appellants. Defendant was charged under the Apothecaries' Act, 1815, for illegally using the title of M.D., and carrying on the practice of an apothecary in contravention of the statute. The defendant proved that he was a registered chemist, and after the first witness had been examined he admitted prescribing and selling medicines to him and to others. No visiting was alleged to have been made. The judge took time to consider the law upon the question, and on the 29th ult. gave a verdict against the defendant for £20 and costs. Mr. Morgan Howard, Q.C., and Mr. Pollock were for the Association, and Mr. Prentice, Q.C., and another counsel defended. The jury was dispensed with, as Hamilton relied upon the question of law.

Students Holiday Reports.

The *Students' Journal* tells us that the parents and guardians of the pupils of the London Dental Hospital will, in future, at the close of each Session have a report sent to them of the number of lectures, &c., attended by their sons.

A series of articles is now appearing in *Nature* on "The Density of Liquid Oxygen," by Professor J. Emerson Reynolds, of the University of Dublin, in connection with the magnificent experiments by MM. Cailletet and Pictet.

Opening of the Medico-Legal Conferences at the Morgue.

THE majority of medical men have necessarily to acquire a knowledge of medical jurisprudence theoretically from books or lectures. The utilisation of the *Morgue* for practical instruction, marks a very important era in French medical jurisprudence, and the Faculty have filled up a void in teaching, which cannot but be productive of good, not only to society but to young practitioners.

Dr. Brouardel has been entrusted with the course, and his appointment has given satisfaction to the French press. The course of lectures is open to students under certain conditions, and as the objects are science, truth, justice—the motto for the student is, *Aude, vide, tace.*

Dr. Brouardel, in his introductory lecture, after thanking the eminent experts, as Tardieu, &c, for their encouragement, impressed upon his hearers the necessity of discretion in observing as secrets what passed at these conferences, as otherwise justice might be defeated, and painful family revelations transpire. His programme is practical. The students will assist the medico-legal experts, prepare notes, and draw up medical-legal reports which will be corrected and discussed. The attention of the authorities in the London, Dublin, and Edinburgh schools of medicine might usefully be directed to the example set by our neighbours. We have not a *morgue*, but we might possibly utilise the materials we have at our disposal, and which are daily furnished in the beforementioned centres.

Imaginative Vision in Hysteria.

AT one of his late conferences at the Salpetrière, Prof. Charcot directed the attention of his hearers to some derangements of vision habitually observed in hysteria, of which there is an interesting account in *Le Progrès Médical*, Jan. 19th. He examined and exhibited several patients of whom the following are examples.

1. M——, often sees grey or black rats running on her left, over the floor, or the drapery of the bed. Hemianæsthesia with dyschromatopsy of the left eye.

2. W——, is often troubled by a vision of lions, on recovering from an attack, they always appear on the left side. Complete anæsthesia and achromatopsy of left eye.

3. V—— sees, in the interval of her attacks, a black cat, sometimes a white phantom. Complete anæsthesia and dyschromatopsy of left eye.

4. B——, even when in a state of calm is often terrified by the sudden and unexpected appearance of a large, grey cat on her right, which seems ready to jump on her, and of which she can almost feel the contact. Hemianæsthesia.

5. Angela —— had almost completely lost her sight in childhood: when threatened with an attack, she imagines she sees *red men* (very much more natural objects for an hysterical person to see than cats or rats).

Sheridan le Fanu has very terrribly and vividly painted the effects of a diseased imagination in conjuring up before the vision forms, as that of a monkey, &c., and though "In a Glass, Darkly," is only a novel, yet—as we see by the experiences of Charcot—it has a scientific basis, and the terrible tales are not so improbable as many readers would imagine.

French Tribute to the late Dr. Stokes.

THE leading organ of the profession in France, *Le Progrès Medical*, has gracefully and justly recorded the loss which the profession of Great Britain has sustained by the death of the eminent Professor of Medicine of the University of Dublin.

Dr. Stokes, in his lifetime, did not receive the rewards due to his talents and European reputation; it is, therefore, gratifying to find that his merits were appreciated by our neighbours. Our contemporary thus concludes an eloquent obituary:—

"Son enseignement hospitalier était très suivi à Dublin et beaucoup des plus connus en Angleterre dans la profession medicale, lui doivent une partie de leur savoir Stokes était arrivé à acquérir la richesse par sa clientele étendue et les honneurs universitaires par son savoir. *Il se souciait peu du reste des titres de parade qu'il ne recherchait pas, et qu'on n'était guère disposé a lui offrir, car il était resté Patriote Irlandais, fidèle aux traditions de sa famille, préférant son independance et l'estime de ses confrères, aux distinctions honorifiques auxquelles son savoir lui donnait tous les droits.*"

Telegraphic and Telephonic Examination of Patients.

OUR contemporary, the *Students' Journal*, remarks that a recent discovery in telegraphy is likely to cause a revolution in medical practice. Hitherto it has been necessary for country patients who wished to consult a London physician, either to come to town, or to send for the physician to visit them at their country homes. But it is not improbable that, before long, physicians will be able to remain in their consulting rooms, and be kept advised by telegraph as to the exact state of their patients without regard to distance. It is reported that a Yankee physician, Dr. Upham, of Salem, Massachusetts, recently demonstrated to an audience, to whom he was lecturing, the variations of the pulse in certain diseases, by causing the lecture room to be placed in telegraphic communication with the City Hospital, at Boston, 15 miles distant; and then, by means of a special apparatus, and a vibrating ray of magnesium light, the pulse-beats were exhibited upon the wall. By a judicious combination of Dr. Upham's apparatus and the telephone, a patient may possibly be subjected to a physical examination sufficient to diagnose heart and lung disease, without going near the physician.

THE mortality from small-pox in London was greater last week than in any corresponding period since June last, 55 deaths having resulted from this disease alone.

ST. PETERSBURGH is still in the unenviable position of being the most unhealthy city in Christendom. Its death-rate is now at 53 per 1,000 of the population, more than double that of London, and exceeding by 10 and 12 per 1,000 even Calcutta and Bombay.

Oxyuris Vermicularis in the Skin.

THE (*Berl. Klin. Wochensc.*), narrates the case of an apparently healthy boy, thirteen years old, who was brought to Professor Michelson suffering from an eruption that resembled an eczematous intertrigo of the genito-crural fold, and encroaching upon the scrotum and thigh. The cause of the eruption was at first not apparent; but, upon microscopical examination of the crusts and scales, he found eggs and embryos of the oxyuris vermicularis in various stages of development. Further examination of the patient, showed that the parasite had been conveyed from the rectum to the seat of the eruption through the medium of a soiled shirt-tail. Warm baths and a dusting powder consisting of one part salicylic acid and one part starch relieved the cutaneous difficulty in a few days.

Symptoms of Intestinal Obstruction.

IT is erroneous, observes Hensgen (*Deutsche Medizin. Wochen*, December, 1877), to assume that obstruction is always accompanied by fæcal vomiting. This is impossible in occlusion of the upper portions of the small intestine, nor has it been confirmed in all cases of closure of the large bowel. In illustration of the latter fact, Hensgen cites a remarkable case of ileus, the most striking feature of which was the long duration of complete closure of the descending colon, namely, forty-four days, during which time nothing passed from the bowel, and also an entire absence of any escape of the intestinal contents upwards, either fæcal, or gas having a fæcal odour. The absence of fæcal vomiting must be regarded as due to the action of the ilio-cæcal valve, which also sufficiently accounts for the non-distension of the small intestine observed in this case.

Phosphide of Zinc in Hysteria.

GROS, in *La France Médicale*, extols this article, and advises its use in nervous affections, and especially in hysteria; giving at the same time a long list of neuroses in which it has been successfully used by physicians in America and England. He says that, though hysteria is an affection strange in its termination, so many cures have been reported that we should prefer this remedy to others because of its promptness of action, its facility of administration, and its innocuousness. It is stated that, contrary to expectation, it is innocuous, because if a toxic dose is given vomiting invariably occurs, which prevents the poisonous action of the drug. The best form for administration is the granule.

THE alarming rapidity, says *Nature*, with which short-sightedness is increasing among German students formed the subject of a recent debate in the Prussian parliament. From extended observations made in the gymnasia, it appears that the number of the shortsighted increases from 23 per cent. in the first year to 75 per cent. in the ninth or last year. The too-frequent custom in Germany of forcing lads to study during the evenings with insufficient light, in ill-ventilated rooms, is undoubtedly a main cause of this widespread evil.

A REPORT has been going the round of the papers that the authorities at the Cape are at their wits' end for army surgeons. Our inquiries do not confirm this intelligence. The field hospitals have scarcely been called into requisition, and as the active force is mainly composed of colonists, having civil surgeons amongst them, the difficulty, if any exists, is very slight.

THE death-rate last week in the four principal cities of the United Kingdom was at the rate of 26 per 1,000 of the population in London, 28 in Edinburgh, 30 in Glasgow, and 33 in Dublin. Of the large towns in the second category, Liverpool 30, Salford 31, Manchester 31, Plymouth 33, and Norwich 41, showed the highest rate of mortality, whilst Hull gave the most favourable returns, 18 per 1,000.

CÆSAREAN section was successfully performed last week, at Guy's Hospital, by Dr. Braxton Hicks, upon a woman whose vagina was occupied by a scirrhous mass affecting both the rectum and recto-vaginal septum. The child was removed alive, but slight hæmorrhage occurring, and the uterus contracted firmly after removal of the placenta.

Mr. R. BROCKLEBANK, President of the Seamen's Orphanage, Liverpool, has offered to bear the entire cost of the erection of a sanatorium or hospital in connection with that institution. The estimated amount is about £3,500.

THE sum of £7,500 has recently been bequeathed by a colonial lady to the London School of Medicine for Women.

Correspondence.

HARVEY'S DISCOVERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of Dec. 12th, you have given Dr. Robert McDonnell's Address to the Surgical Society of Ireland. The uncomplimentary remarks then uttered we do not wish to notice; but, we courteously challenge him (in the accompanying letter), to make good his assertion that Harvey's Discovery was made by experiment on living animals.

I am, Sir,
Your obedient servant,
GEORGE R. JESSE,
Hon. Sec., Treas. and Member of Council
of the Soc. for Total Abolition of Vivisection.

FROM MR. JESSE TO DR. R. MCDONNELL.

SIR,—Will you permit us to direct your earnest attention to the accompanying pamphlet on some of the discoveries attributed to vivisection.

We believe that the assertion in your address (delivered before the Surgical Society of Ireland, on the 23rd Nov. last), in regard to Harvey and the circulation of the blood, was not founded on a mature consideration of the subject. We believe that no able surgeon can, after mature reflection, be of opinion that the discovery of the circulation was made, or could be made, by the dissection of living animals.

Allow us to courteously invite you to carefully peruse, and,

if possible, refute, the facts, argument, and testimony contained in our pamphlet.

I am, Sir,
Your obedient servant,
GEORGE R. JESSE,
Hon. Sec., Treas. and Member of Council.

To Robert McDonnell, Esq,, M D., F.R.S.,
Pres. of the Roy. Coll. of Surg. in Irel.,
14 Lower Pembroke St., Dublin.

P.S.—We beg leave to say in regard to an accusation made in your address, the advertisement (which appeared repeatedly in the *Morning Post* and the *Times*, in April and May, 1877), will prove the Society disavowed the revolting illustrated placards exhibited in the streets of the metropolis, and inserted in the *Police News*.

FROM DR. MCDONNELL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Before you were good enough to forward to me the accompanying letter from Mr. George R. Jesse, I had already received from him a copy of the pamphlet, entitled "Violationism," and a letter identical with that which you enclose, "courteously inviting me to carefully peruse, and, if possible, refute, the facts, argument, and testimony in this pamphlet."

My address delivered before the Surgical Society of Ireland, and already published in your columns (and also in a separate pamphlet form, by Messrs. Fannin and Co., 41 Grafton Street, Dublin), is intended to be a refutation of Mr. Jesse's facts, argument, and testimony.

I believe that thoughtful persons who are capable of dispassionately weighing evidence on such subjects, will find, in the pages of this address, a tolerably satisfactory reply to Mr. Jesse. I am not vain enough to venture to hope to change Mr. Jesse's views. Those who are sufficiently interested in the subject to do so must read his pamphlet and my address, and after reflection, determine where the truth lies.

Mr. Jesse does not believe that Harvey discovered the circulation of the blood by experiment on living animals: on the other hand, we have undoubted evidence that Harvey himself believed that he had done so. Now, on this question I conceive that most persons will agree that Harvey was the best judge.

Mr. Jesse believes that no able surgeon can, after mature reflection, be of opinion that the discovery of the circulation was made, or could be made, by the dissection of living animals; at page 21 of his pamphlet, he says, "the circulation cannot be *demonstrated* by vivisection." Yet, every one who has seen the circulation going on under the microscope knows that it is thus, by experiment on a living animal, demonstrated as clearly as persons walking at noonday in the streets of London.

I consider it, therefore, useless to prolong any correspondence on this subject, as it appears to me that Mr. Jesse's mind is not open to that kind of evidence which is convincing to most people.

I am glad that Mr. Jesse is able to disavow the "revolting placards" exhibited in the streets. It would, after his disavowal, be unjust to suppose that he belongs to that group of fanatics "who placarded our walls with sensational diagrams;" he seems to fall merely within the next category to which I allude—viz., those who advertised in our newspapers, offering bribes for secret information.

I must here beg leave to close a correspondence which I feel will prove of little benefit to either of the contending parties.

I have the honour, &c.,
ROBERT MCDONNELL, M.D.

14 Lower Pembroke St., Dublin,
February 11th, 1878.

SIR M. H. BEACH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think many of your readers wish that you had not departed from the very wise rule which excludes politics from the pages of your journal. I for one strongly object to have a column and a half filled with adulation of Sir M. H. Beach. Eulogy, too, of the man and the *regimé* that have done so much to make the position of the Poor-law medical officers of this country well nigh intolerably irksome, and our sanitary legislation and administration a broad farce!

Allow me to record a few instances of the "firm principle" possessed by our late president of the Local Government Board for Ireland. He dismissed a Poor-law medical officer for mildly drawing public attention to the inconsistencies of the board over which he was president; and then alarmed at the act, withdraws the hasty order of dismissal. He told a dispensary committee that they were illegally constituted, and warned them that they must not do a certain act; they disregard his admonition, and he approves their action. He told the dispensary doctors that red tickets issued under certain circumstances were illegal, but if they do not choose to attend them he will dismiss them. He acknowledges certain duties are put on Poor-law medical officers which they could not have undertaken to discharge when they were appointed, as the duties did not then exist; yet if they murmur they must resign or be dismissed. Hardly an issue of the MEDICAL PRESS AND CIRCULAR but contains evidence of his ignorance, or his inconsistency, or his petty tyranny in dealing with the medical gentlemen subject to his board. Of his Chief Secretaryship, I shall say nothing, except that it appears to me to have been just as far as it could from the Millennium which you describe. It would not be difficult to substantiate this opinion, but that I hold the rule of "no politics" is too inviolable to be in abeyance for even one more issue of the MEDICAL PRESS.

Yours faithfully,
A PROTEST-ANT.

[We have no concern whether a minister is the officer of one political party or the other; but we have an interest in the departure of a member of the executive who had shown himself willing to hear and give effect to the representations on behalf of the profession. The "Protest-ant" who writes to us knows quite well—if he knows anything of the subject—that Sir Michael Beach had about as much to say to the acts of the Local Government Board as the Queen has to a local tramway bill. He was nominally answerable for the deeds of the board, but actually totally ignorant of them, and we anticipate that few of our readers will hold him responsible for omission to interfere in the internal management of a department with which he is only theoretically connected.—ED. M. P. & C.]

MEDICAL WOMEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Sentiment and reverence for old ideas have received such powerful denunciation that one would have thought those feelings had received a *coup de grâce*. Their vitality is however proved by the attitude, both of some medical men and of part of the medical press, who are so prejudiced as to regard women as only fitted for child-bearing and domestic work, and who consider the commingling of the sexes demoralising. It is time we looked at this question apart altogether from artificial distinctions and associations. The difference between man and woman is a *pure accident*, and we should only look at the subject from the brain side, and also from the politico-economic side. I think we are all agreed on some points. A large number of women have not as much brain capacity as man; but a very large number have equal capacity, and a certain proportion have a higher capacity than the average of men. I need not enumerate all the eminent women who have lived, but as instances of brain capacity I may cite the authoress of "Daniel Deronda," and "Middlemarsh." I presume few will deny that Mrs. Garret-Anderson has brain power certainly equal, if not superior, to that of the average medical man, and therefore the special fitness of some women for the acquisition of medical knowledge is proved. As regards delicacy, I have not the slightest doubt women are better judges on this point than we are; and it seems, to use a mild phrase, "unscientific" to talk about prudence, decorum, unwomanly women, &c. We are not the guardians of virtue, or of rules of propriety. Do the lecturers and press look after the morality of the male students? Are medical students distinguished for their very high sense of some of those graces called chastity, continence, temperance, sobriety, &c.? Does Smith, who objects to associating in a lecture-room with a highly educated lady, equally object to his receiving his matutinal glass of beer and smiles from the maidens at the *restaurant* patronised by the hospital?

A woman behind a bar is tolerated and often idolised by the same young fellow who is ready to insult Miss S. in the lecture-room. Strange perversion of the male intellect,

caused by custom and habit! Women have to work in the world, and to contend with men in the struggle for existence in businesses, requiring energy, tact, financial skill, and other essentials for success; and they compete and hold their own, so that if we have the necessary primary brain power, they will also hold their own in the medical arena.

2ndly. It will become a question of supply and demand. If medical women are wanted, they will be forthcoming. If they are not supported by the public the movement must die a natural death. There was once an objection to employing female nurses for men. They are now almost universal; custom has consecrated them, the so-called immorality being forgotten. Sisters of Charity, and sisterhoods in general, were also opposed. Few will deny that they have given a higher tone to nursing, and also exercised a beneficial influence on the students.

The *morale* of the medical student is not perfect, to say the least of it; and if there is danger of his mind becoming contaminated, or losing its virgin purity, by sitting alongside a female student—

"Some sweet girl-graduate with golden hair—"

he must have altered very much from the student of my time. I might even hope, that as the presence of ladies has a controlling influence over men in ordinary life, in checking lewd and indecent conversation, &c., lady students might exercise a beneficial and much needed influence in some of the schools of medicine. It is a simple matter to a range for special lectures on special diseases.

Women have a right, and only ask for

FAIR PLAY.

London, Feb. 12, 1878.

THE LATE DRS. STOKES AND FLEETWOOD CHURCHILL, OF DUBLIN.

AT the meeting of the Dublin Medical Society, held on Wednesday, the 6th inst., Dr. Fitzpatrick, Vice-president, occupying the chair.

Dr. Duffey (hon. sec.), reported that since the last meeting of the Society, it had lost two of its most distinguished members, one of its Vice-president, Dr. Wm. Stokes, and another very well-known member, Dr. Fleetwood Churchill.

Dr. Henry Kennedy said it had fallen to his lot to move a vote of condolence to the families of Dr. Stokes, and Dr. Churchill. He need not speak in reference to the character of Dr. Stokes. He was universally known, and was respected by all. His death was probably the greatest loss the college had sustained in the last quarter of a century at least. He was a Vice-president of the Society for years, and as long as he was able, he was always a steady attender at the meetings, a very important point in these times, and one that ought not to be forgotten.

Dr. Churchill always occupied a high place, although not mixing among the members of the Society, so much as Dr. Stokes, owing to the nature of his practice. Still he was very often present at their meetings, and always took an active interest in all their proceedings. He was sure the meeting would pass the following resolution by acclamation. "That at this, the first meeting of the Medical Society of the College of Physicians, held since the lamented deaths of Dr. Stokes, one of the Vice-presidents of the Society, and of Dr. Churchill, the Society desire to express their sense of the irreparable loss sustained by the removal of two such distinguished members, one the leader of Irish medicine, and the other amongst the foremost of the cultivators of obstetric science, and that the secretary be requested to convey a message of condolence to the relatives of the deceased."

Dr. M'Swiney seconded the motion. He concurred in the propriety, as he was sure also the meeting did, of this Association passing such resolutions. The name of Dr. Stokes would ever be associated with the Irish School of Medicine as its great ornament of this century, as long as the English language was spoken. He could not speak of Dr. Churchill from a personal knowledge extending over a quarter of a century, and he could say that a more kindly good natured friend and medical colleague, it would be impossible for anyone to meet, than the late Dr. Churchill was. All those who were his pupils, and subsequently such of them as became his colleagues, or were associated with him in this city, where he practised, were well aware, for it was notorious, that he was ever ready to offer his services in the kindliest and most unselfish way to the junior members of the profession, on all occasions of trouble or difficulty, or on any occasion when his assistance might be valuable. His nature was kind, his intellect accomplished, and in every department of life, public, professional, and private, Dr. Churchill was everything that could be desired.

Dr. Fitzpatrick said it seemed an appropriate accident that he should occupy the chair that evening, as he was certainly the oldest pupil of Stoke's present in that meeting, and probably, if the members present were doubled, he should still not be deprived of that privilege. It was now 45 years since he entered the Meath Hospital, under Stokes and Graves, and that year was he should say most remarkable in this respect, that in consequence of the difficulty of dissections in England, they had a most numerous class of English students at the Meath, probably there had never been so large a class since, and the result of that was the Irishmen, were stimulated to such an amount of energy, and to the performance of such an amount of work, that poor Dr. Stokes had told him that he had never witnessed at that hospital the like of it at any subsequent period. He would not add one word to what had been already said, which simply re-echoed what had been said by the periodicals of these and foreign countries in relation to the character of Dr. Stokes. As Dr. M'Swiney had very properly observed, his name would be remembered as long as the English language was spoken in Ireland, and he, perhaps, was without exception the most energetic man in forwarding the interests of the Irish School of Physic. With regard to his (Speaker's) friend Dr. Churchill, who was perhaps more a contemporary than Dr. Stokes, he could only say that in all his experience of him, he never met a more kindly good-natured practitioner than he was.

The motion was passed unanimously.

Obituary.

CLAUDE BERNARD.

ONE of the most illustrious of physiologists has just passed away. *L'Union Medicale* says, that he died at 65 years of age, from an insidious disease, the gravity of which, and in fact, even its existence had scarcely been detected.

Claude Bernard was incontestably the chief of physiologists of all nations. His discoveries upon the function of the pancreas and liver; his experience upon the production of diabetes by puncture of the fourth ventricle; his researches upon poisons, and notably upon curare, have immortalised his name, whilst an infinite number of other studies and publications would have sufficed to render him celebrated.

Claude Bernard was the pupil of Rayer, and the *protegé* of Magendie, who made him his curator in the College of France.

As soon as he obtained the degree of doctor of medicine, and doctor of science, he devoted himself incessantly to his favourite study, and three times obtained the grand prize of the Academy of Science, in physiology.

At the death of Roux, he was nominated to the Academy in the section of medicine and surgery.

Claude Bernard belonged doubly to the Institute, by the Académie des Sciences, and by the Académie Francaises. He was a member of the Académie de Medicine, section of Anatomy and Physiology. Perpetual President of the Societé de Biologie, and member of all the important foreign learned societies. He was decorated by the Emperor with the order of the Legion of Honour. He published numerous works, most of which were a re-

production of his lectures, but which as regards their influence upon the science of physiology, have not been surpassed by any other writer. Claude Bernard devoted himself to study, and avoided politics.

Simple, modest, an attractive teacher, and encouraging the young to learn, he leaves a memoire, illustrious, beloved, and honoured. His life by scientific research, was devoted to the welfare of his fellow creatures; his death is a public, a universal regret.

THE COLLEGES OF SURGEONS AND THE DENTAL BILL.

In a justly condemnatory article respecting this Bill, published in its last issue, the *Lancet* says: "The worst feature of this extraordinary business is the false position in which the Colleges of Surgeons, we regret to find without exception, have placed themselves with regard to their Fellows, Members, and Licentiates. The prospect of an increase in the number of practitioners seeking their special diplomas would seem to have over-borne every consideration of test and honour." It is a serious accusation to make that the Colleges have sacrificed their "honour," and the interest of their "Fellows, Members, and Licentiates," to the greed of gain; and we can speak, we believe, with certainty, when we state that *quoad* the Irish College of Surgeons at least such a statement is calumnious. The Council of that College has not had the complete Bill before it, and has not expressed any official opinion thereon. Representations which conveyed to the Council a totally inaccurate impression as to the nature of the measure, were made to the College some months ago; and, under this misapprehension, the Council, we believe, inferred, rather than gave, a sort of consent under the strictest reserve as to its future action in reference to the Bill. We shall be much surprised if the Council, being now informed of the nature of the measure, does not at once take steps to annul the semi-approval which it was induced to give.

A SERIOUS WANT IN THE ARMY.

It has been known in well-informed medical circles that for the past few years there has been a serious dearth of candidates for the Army Medical Service, notwithstanding the latest bid of the Government to give a bonus of £1,000 on retirement after ten years' service. Were war to break out at the present time the patriotism of the profession would doubtless rise to the emergency as it has before, and ungrudgingly place its full quota at the service of the Government. But it is unwise in so vital a question to trust to the game of chances, and the Secretary for War, fully recognising the gravity of the situation, deplored, in the House on Monday night, the fact that for forty appointments only nineteen candidates had presented themselves, promising at the same time to inquire into the subject. We hope that when the Right Hon. gentleman fulfils his promise the evils of the existing system which have been so often pointed out in our columns, will be honestly brought under his notice, the remedying of which can alone remove those objections to join a service which was once so popular with young men in the profession.

NOTICES TO CORRESPONDENTS.

Association of Dental Surgeons.—This evening, at 8½ p.m., Mr. Lyons will read a paper, "Observations on the Treatment of Compound Fractures of the Lower Jaw."

Harveian Society.—Thursday, Feb. 21, at 8 p.m., Dr. G. de G. Griffith, "A Case of Hydramnios," and Mr. K. Thornton, "On Unsuccessful Ovariotomy."

An Intending Candidate.—The next examination for the M.R.C.S.E. will commence on Friday, March 29. Certificates must be forwarded to the Secretary at the College on or before the 22nd March. There will also be another examination on April 23, certificates for which must be forwarded not later than the 12th April.

Ladies' Lockjaw.—Our contemporary, the *Students' Journal* of Feb. 16, is responsible for the following:—"Abernethy being called one day to attend a lady who had severely cut her hand, was much annoyed by her protestations that she knew she should die with lockjaw. 'Die with lockjaw, madam,' said he, encouragingly; 'I never yet knew a *woman* to die of *lockjaw*.'"

CAUSE OF DEATH DURING TRACHEOTOMY.

To the Editor of the Medical Press and Circular.

Sir,—The freedom with which, under artificial respiration, air passes the canula, is, of course, the practical test of the occurrence of such an accident as that described by Dr. Brandies in your issue of Feb. 13, or of that in which the layer of diphtheritic exudation yielding and becoming detached before the point of the knife, is not divided or is pushed downwards forming a plug.

Yours faithfully,
London Hospital Medical College, February 15th. Norman Chevers, M.D.

Dr. T. F. W.—Sorry we cannot oblige you.

A Bartholomew's Student.—The work from which the quotation is taken is of German origin, subsequently translated and published by an American house. You would probably get a copy at one of the foreign booksellers in London.

A Retired Army Surgeon.—We can recommend no particular agent. You had better satisfy yourself by independent inquiries before purchasing a practice.

A special Evening Meeting of the Pharmaceutical Society of Great Britain will be held on this Wednesday evening at 8 o'clock. Prof. Redwood will deliver a lecture on "Spectrum Analysis," illustrated with the Electric Light.

County Dublin Light Infantry.—Dr. Alexander Phayre, 76 Harcourt street, has taken over medical charge of the permanent staff of this regiment.

VACANCIES.

Balrothery Union, Lusk Dispensary.—Medical Officer. Salary, £123. Election, March 2.

Cork District Lunatic Asylum.—Assistant to the Resident Medical Superintendent. Salary, £110, with apartments and allowances. Election, March 1.

Downpatrick Union, Strangford Dispensary.—Medical Officer. Salary, £100. Election, Feb. 21.

Gort Union, Ardrahan Dispensary.—Medical Officer. Salary, £140. Election, March 14.

Killala Union, Killala Dispensary.—Medical Officer. Salary, £60. Election, March 2.

Milford Union, Ramelton Dispensary.—Medical Officer. Salary, £115. Election, Feb. 25.

Portumna Union, Eyrecourt Dispensary.—Medical Officer. Salary, £120. Election, March 1.

South Charitable Infirmary, Cork.—House Surgeon and Apothecary. Election, March 8. (See Advt.)

Marriages.

Kennefick—Hamerton.—Feb. 9, at Orchardstown, Clonmel, John S. Kennefick, M.D., Clonmel, to Malvina, youngest daughter of the late General John Millett Hamerton, C.B., Colonel of the 55th Regt.

Wilkinson—Battiscombe.—Feb. 14, at St. James's, Kidbrooke, Kent, J. Cooper Wilkinson, M.R.C.S., of Ashford, to Frances, daughter of the late Rev. Hy. Battiscombe, M.A., of Blackheath.

Williams—Turner.—Feb. 14, at St. James's, Bermondsey, S.E., Alfred D. Williams, M.B., of Demerara, to Annette, daughter of W. H. Turner, M.R.C.S.

Deaths.

Bleeck.—On Feb. 4, at Warminster, Charles Bleeck, Surgeon, aged 72.

Graham.—On Feb. 7, at Belfast, Charles Graham, late House Surgeon Convalescent Hospital.

McCarthy.—On Feb. 7, at Clonmel, Anastatia Teresa, the beloved wife of Charles William McCarthy, M.D.

Norris-Cane.—On Feb. 8, at Carlow, of diphtheria, Mary Joseph Anne (Nandy), eldest daughter of Dr. J. B. Norris-Cane, of Mullinavatt, aged 7 years. (Job. i., 21).

Porter.—On Feb. 3, at Peterborough, William George Porter, Surgeon, aged 57.

Thwaites.—On Feb. 4, at Bishop-Auckland, Thomas Bowe Thwaites, M.R.C.S.E., aged 58.

Wickham.—On Feb. 5, at Clapton, Edgar Wickham, M.R.C.S.E.

IRISH POOR-LAW INTELLIGENCE.

THE ENFRANCHISEMENT OF PAUPERS IN IRELAND.

Our attention has been directed to one clause of a very innocent-looking Bill (section 11, of the Parliamentary Franchise Bill introduced by Mr. Meldon and Mr. Mitchell Henry) now before the House, which clause is of very serious import to the Poor-law Medical Officers of Ireland. The section in question simply repeals the provision of an Act (Parliamentary Voters' Act, 13 and 14 Vict. cap. 69, sec. 111) which refuses the franchise to persons in receipt of poor relief. Upon consideration of this the Council of the *Irish Medical Association* has addressed the following letter to the Attorney-General for Ireland:—

TO THE RIGHT HON. THE ATTORNEY-GENERAL FOR IRELAND.

Sir,—I am directed by the Council of the Irish Medical Association to request your attention to the 11th section of the Parliamentary Franchise (Ireland) Bill (now before the House, and standing for a second reading on the 13th inst.), which section provides for the repeal of the 111th section of the 13th and 14th Victoria, cap. 69. This section, which it is proposed to repeal, enacts "That no person shall be entitled to be registered in any year as a voter in the election of a member or members to serve in Parliament . . . who shall within twelve calendar months next previous to the . . . 20th day of July of the current year, have received relief under the Acts for the more effectual relief of the Destitute Poor in Ireland."

The effect of the passing of the 11th section of the Bill now before Parliament would be that persons would be still entitled to all the privileges of the franchise notwithstanding that they were recognised as poor persons by the Medical Charities Acts for Ireland. I beg to remind you that by the 9th section of the 14th and 15th Vict., cap. 68, the medical officer of a dispensary district is obliged "to afford medicine and advice" to any "poor person" resident within the district who shall present him with a ticket, and the vagueness of the word "poor," as describing the recipient of gratuitous medical relief, has been availed of very usually by persons who are not in any just sense entitled to gratuitous relief, and who thus obtain unremunerated attendance at the expense of the medical officer, and gratuitous medicine and medical appliances at the expense of the ratepayer. The only restriction which the law has hitherto imposed upon this abuse of the medical charities system is the disfranchisement which follows upon poor relief, and that restriction has hitherto been effectual in preventing the better class of farmers from seeking gratuitous medical attendance and medicine. The Bill to which I refer, if permitted to become law, will remove this restriction, and inasmuch as experience proves that in many districts medical relief tickets are readily obtained by persons in comfortable circumstances, the benefits of gratuitous advice and medicine will be freely opened to such people, I am therefore desired to express the earnest hope of the Council of the Medical Association that the influence of the Government will be exerted to prevent a measure so unjust both to the ratepayers and the Poor-law medical officers from becoming law.

I am, Sir, yours faithfully,

A. H. Jacob.

We call attention to the subject in order that each Poor-law Medical Officer may aid the Association by communicating directly with the representatives of his own constituency. It would indeed be intolerable if every farmer in the county were permitted the gratuitous services of medical officers whose duty is confined to the "poor," and were nevertheless privileged to vote for M.P.s and guardians of the Union.

THE IRISH MEDICAL ASSOCIATION AND THE BRITISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE DAILY EXPRESS.

Sir,—In your able article of the 31st ult. upon the newly-formed Dublin Branch of the British Medical Association, certain passages occur which are considered by many members of the Irish Medical Association and of the public to convey erroneous impressions as to the aims, objects, and mode of action of the Irish Medical Association. Referring to the Irish Association, you write: "That society has a special sphere of action, in which it works with great diligence and efficiency. It is an Irish Medical Defence Society, &c." Again, drawing a comparison between the British and Irish Associations, you write: "The British Medical Association, however, has objects which not only are imperial, but have a higher scope and aim than the material welfare of its members." Now, these two statements read together are considered by many to mean (although I feel certain you did not mean in any way indirectly to depreciate the Irish Association) that the Irish Association is merely a "defence association," and has no "higher scope and aim." It is with a view of removing such an impression that I now write, having the full concurrence and by the expressed wish of the Committee of Council of the Irish Medical Association. Admitting that the Irish Association is a defence association, just as its British compeer is, yet I deny most emphatically that it has "no higher scope and aim."

The difference between the two Associations consists mainly in this, that while the British Medical Association and a great proportion of its branches are scientific societies (where papers connected with medical science are read), as well as medical protection and medico-political

societies, the Irish Association embraces only the two latter objects. Medical politics—or state medicine, as it is now more correctly termed—affects the public interest much more than the "material welfare" of the members of the medical profession. It includes all those social questions in which the health and physical condition of the population are concerned, all medico-legal questions, and all the relations of the profession to the public. In all these matters the Irish has been quite as active as the British Medical Association. Not to go far back into the history of the work done by the Irish Medical Association, I may mention that within the last two years the Association has busied itself with the amendment of the law for the registration of births and deaths, the vaccination laws, and the laws affecting the public health, besides many other minor matters. In the case of the first two great questions the Association has, at its own cost, and by the industry of the members of its own committees, prepared bills to be submitted to Parliament. One of these—the Registration Bill—was introduced in the House of Lords, read a first time, and been since approved of by the Government. The other has been favourably received by the Government. In these two bills, while they confer some slight benefit upon the members of the profession, very large and important improvements are proposed in the law, from which the public will derive the whole benefit. In the case of the Public Health Bill, now again before Parliament, I have to state that of amendments to the 56th clause of the bill put forward by me on behalf of the association but six were of any direct benefit to the profession, the remainder being all for the public benefit. I may add that a very large number of these amendments were adopted by the Government, and now form part of the bill before Parliament.

There need not be any conflict between the British and Irish Associations. Their aim differs somewhat, and also their modes of operation; but the aims of the Irish are just as noble, though not so extensive, as those of the British.

I have the authority of Dr. Duffy (Secretary of the Dublin Branch of the British Medical Association) for stating that there is no antagonism between the associations, and that the British will be always willing and ready to co-operate with the Irish Association in all movements for the advancement of the public or professional benefit.

I remain, yours faithfully,

T. W. GRIMSHAW, M.A., M.D.,
Chairman of the Council of the Irish Medical Association.

12 Molesworth Street, Feb. 7th, 1878.

DUNGARVAN UNION.

MR. DEE reported that the dispensary doctor, Dr. Anthony, was confined last week to his bed, and he called on Dr. Hunt in a serious case of midwifery, (Dr. Hunt) had also to do three days' dispensary duty, for which he charged five guineas.

Mr. Terry—I think it is Dr. Anthony's duty to pay him.

Mr. Fitzgerald—Two guineas he is entitled to.

Capt. Curran—Dr. Anthony has done duty in this house for Dr. Hunt, and he did not charge.

Mr. Fitzgerald—I would give them two guineas.

Capt. Curran—I would not give him two farthings.

Mr. Fitzgerald thought he should be paid two guineas for the case of midwifery, and 10s. a day for the rest.

Lord Stuart—Do you think that £3 would be enough for him?

Mr. Curran thought not.

Mr. Terry said it was a bad precedent to pay doctors any more than their salaries.

The Clerk suggested that as Mr. Dee in his report had made out two distinct cases, it would be well in the order to say that as the midwifery case appeared to be part of the ordinary duties, they decline to pay any more than two guineas.

Mr. Wall thought this too much.

It was ordered that as the midwifery case was part of the dispensary duty, and as three guineas is the usual recognised salary during the illness of the dispensary doctor, they consider three guineas the outside sum that they can be requested to pay, and they order the payment of three guineas accordingly, subject to the opinion of the Local Government Board.

Mr. Curran said, in order to avoid occurrences of this kind for the future, if there was a resolution put on the books, refusing payment unless the doctor is authorised to act.

Lord Stuart said they should make an allowance in cases of urgency.

MOUNTMELLLICK UNION.

DR. WILKINSON'S SUPERANNUATION.

THE Local Government Board forwarded a list of queries to be answered by the Clerk touching the proposed superannuation allowance to Dr. Wilkinson, late medical officer of the Clonaslee dispensary district.

Mr. Phillips handed in a notice of motion that he would on the 16th of March next move that Dr. Wilkinson's superannuation be increased by the sum of £34 1s. 1d., to make up the sum of £86 1s. 1d. to which he was entitled.

Mr. W. H. Cobbe thought the Chairman could not receive that notice, or re-open the question after it has once been decided by the board,

Chairman—You cannot reduce, but I think you can increase.

Subsequently, Mr. W. Cobbe handed in a counter notice of motion to Mr. Phillips's to the effect that he would, on the day named, move that the board decline to give Dr. Wilkinson any pension, "as such pensions to officers of the union told heavily against the principle that had to guide the farmers and ratepayers in making provision for old age and infirmity."

THE DEATH OF DR. PELLY, OF EYRECOURT

AT a special meeting of the Eyrecourt Dispensary Committee, it was resolved, "That this committee do express their most profound regret at the death of their truly kind, attentive, and talented medical officer, Dr. Pelly. During the fifteen years that Dr. Pelly attended the dispensary districts of Eyrecourt and Killimore, he discharged his duties to the sick and suffering poor faithfully and well. We deplore his death the more, as his fatal disease was caught in the fearless discharge of his professional duty. We tender to his afflicted widow and her helpless charge, also to his relatives, our deepest sympathy in their irreparable loss.

DROGHEDA UNION.

SANITARY.

THE following letter was read:—

DEAR SIR,—In compliance with the request that I should furnish to the Board of Guardians, Drogheda Union, an explanation of a short note in the quarterly return ending 31st December, 1877, made by me to the Registrar General to the effect that I believed the Sanitary Act to be "good in theory but very faulty in practice," I beg to say my observations had no reference to the working of the Act in my district in particular—I refer to the Act generally.

As I have been called on to explain myself I shall do so as shortly and concisely as possible.

I believe any Act of Parliament having for its object the safety of the people, is good in theory; however it doesn't follow that the working of it may not be faultly in detail as I put in practice. There can be no doubt that the in-

tention of the legislature was to strive in this matter after perfection, and to attain as far as possible, and in this in my opinion there has been considerable failure.

I believe, in a town of the importance of Drogheda there should be a Medical Officer of Health, whose sole business would be to act as head of a Sanitary Department; that the gentleman shouid be debarred from private practice, and that he should be paid an adequate salary for this privation. It would be essentially necessary that he should be thoroughly acquainted with "state medicine;" in fact, should be a first class-sanitarian, such as you find in the large towns in England, where a consulting officer exists not in name only, but as a pleasant reality. Again, I believe the Act is faulty in practice in this way. A notice is sent by the sub-sanitary officer to the sanitary officer, calling him to make a report towards having a nuisance removed. This is done; the nuisance is abated, but only to be renewed, and another notice is required, and with the same result. Another fault is that appears to me to exist in the practice of the Act is, that if you condemn houses of the poor, especially in the country, they have no place to shelter themselves, and you have to do a most unpleasant duty—to be a sanitarian, not a humanitarian; and this difficulty is not lessened by the medical officer having to depend so much on his popularity with the poor people. I would have, as I already said, an officer in the town of Drogheda. I would hold him responsible for the working of the Act; otherwise in my humble opinion the Act cannot be satisfactorily exercised in detail. I hope I have made myself understood, and as stated in the commencement of this letter, my remarks to the Registrar-General had bearing only on the Act generally, and not on my district in particular, which, as I have written to the Registrar General, is fairly healthy.

I am yours, &c.,

JOHN L. KIELY.

P. Dowdall, Esq.

The board adjourned.

A WEALTHY PAUPER.

A SUDDEN death took place recently, at the Trim workhouse. An old man, named Malone, who has been for many years in charge of the little lodge at the entrance-gate of the workhouse, died suddenly. When his garments were searched, it is stated that £64 or £74 odd were found.

CARNEY DISPENSARY.

ELECTION OF A DOCTOR.

AT a meeting of the Committee Dr. Robert St. George Roe, the esteemed and efficient medical officer stationed at Cliffoney, was unanimously elected. No other candidate offered.

CASTLEBLAYNEY UNION.

THE committee of Castleblayney Union held a meeting to elect a successor to Dr. Morton, who had resigned.

The candidates were—Dr. Jackson, of Clones, Dr. Clarke, of Jervis street Hospital, Dublin, an dDr. Martin, medical officer, Ballyhay dispensary district. After a short discussion, Dr. Clarke was elected by a majority of two out of 17 votes.

TRILLICK PETTY SESSIONS.

THE SANITARY CASE AT DROMORE.

WM. L. CRAWFORD, sanitary sub-officer of the Omagh Board of Guardians, charged Jane Hutchinson, Rahoney, with neglecting to provide the necessary maintenance for her children, whereby their lives are endangered.

The defendant had appeared at last Petty Sessions to answer a charge of allowing her dwelling-house to remain in a dilapidated and dangerous condition. She was then ordered to have the house repaired within a certain time.

Mr. Crawford now stated that he had visited the house that morning, and could see no food in it. Dr. Duncan, Fintona, had also visited the house—Dr. Marshall, Dromore, being ill.

Dr. Thomas Duncan deposed that he saw the children in the house that morning. They were in a very bad state, and seemed to get little or no nourishment. Two of the children would eventually die of starvation if something were not done.

Chairman—Do you think so?

Dr. Duncan—I do.

Chairman—I saw them myself lately, and I think so too.

Mr. Anderson—Has anything been done about the former case?

Mr. Crawford—Nothing has been done as yet, and she has no intention of doing anything.

Chairman—She has got to the 17th of this month to fix the house.

Dr. Duncan said the house was in such a filthy condition it might create a fever.

Mr. Crawford said he was of opinion the woman would do nothing in the way of repairing or cleansing it.

The Chairman said he sent the defendant two masons to begin work at the house, and she refused to give them 3s. a day, got her back up against the wall, and would not let them commence work.

The defendant here intimated her willingness to get the repairs executed by men of her own choosing.

Dr. Duncan further stated that he saw the carcase of a calf lying in the house on that morning, and a portion of same in the garden.

Mr. Hugh Graham, guardian for the division, stated that the children, after being pressed on the subject, told him they only got a drop of Indian stirabout once a day.

A daughter of the defendant, about ten years of age, was brought forward and questioned, and she stated that she got enough food. This reply was anticipated by the prosecutors,

Dr. Duncan again stated that the two youngest children could not possibly exist long; they were mere skeletons from want of proper nourishment.

Mr. Anderson (to Dr. Duncan)—What do you think if we postpone the case.

Dr. Duncan—I don't think it would be advisable. I would not guarantee that the two children would be living this day month.

Their worships allowed the case to stand over.

At the conclusion of the other business, the case was again called, when it was found that the defendant had left the Court.

Their worships ordered that the information of the witnesses be taken, and the Law Adviser's opinion be asked, in reference to having a warrant issued for the woman's arrest.

MULLINGAR INFRMARY.

AT a meeting of the Board of Governors of the Westmeath County Infirmary, J. G. Cahill, Esq., M.D., was unanimously appointed hon. surgeon to the institution in the room of Dr. Vandeleur Kelly, resigned.

LIMERICK DISTRICT ASYLUM.

GOVERNMENT GRANTS FOR PAY PATIENTS.

AT the monthly meeting of the Governors, the Chairman said Dr. Courtenay had called his attention to the fact that while the Treasury contributed to the maintenance of paying patients in English asylums, it did not

grant a similar rate in aid to the asylums in Ireland. A resolution was passed requesting the Chairman to communicate with the Treasury on the subject.

WEEKLY REPORT OF HEALTH OF DUBLIN AND SUBURBS FOR WEEK ENDING FEB. 7, 1878.

Total registered deaths in Dublin and suburbs*	...	199
Ten years average of same week	...	198
Excess of mortality above average	...	1
10 weeks ratio of deaths Rathmines	20·0	per 1,000
„ „ „ „ Donnybrook†	28.6	„
„ „ „ „ Blackrock	17·3	„
„ „ „ „ Kingstown	18·3	„
„ „ Entire Dublin District	32·9	„
COMPARATIVE RATIOS—London ...	26·4	„
„ „ Glasgow ...	29·8	„
„ „ Edinburgh ...	28·1	„

* District extends over 10,050 acres, and contains 314,666 persons.

† This district includes City of Dublin and Incurable Hospitals.

The number of deaths from zymotic diseases registered during the week is 26, being 2 less than in the preceding week, and 8 under the average for the sixth week of the last ten years. The deaths from these diseases include 2 from small-pox—2 children aged 4 and 5 years respectively; one was not vaccinated, and the other was stated to have been vaccinated when four months old. Among the remaining deaths from zymotic diseases are 4 from fever (all of the typhoid charrcter) 6 from measles, 4 from whooping-cough, 3 from dysentery, 2 each from croup, diarrhœa, &c.

Bronchitis caused 51 deaths, pneumonia 9, and lung disease unspecified 7. These 67 deaths are 14 over the number of deaths from diseases of the respiratory organs in the preceding week, and 19 over the average for the sixth week of the last ten years.

What is Broussaism?

WE have often been asked this question, and several correspondents have applied for information, probably owing to the appearance of a paper in a contemporary. Broussais's aphorisms or principles of medicine, fifty years ago, created a sensation not only in the French but in the English medical world; and though they were not free from error, they exercised a very considerable influence on medical thought. A very good translation of them may be found in the *Med. Chir. Review*, vol. vi, p. 314. In reference to tubercles, Broussais laid down the following propositions:—

167. The tubercles which succeed inflammation of the mucous membrane of the bronchi and their cells, are engendered in the same murmur, as enlargement of the mesenteric glands, in chronic enteritis.

168. I have never seen pulmonary tubercles, without previous inflammation, even those which are found in the lungs of children at birth, do not appear to be independent of this cause.

169. Tubercles form in all kinds of constitutions where chronic inflammation of the lungs or intestines has prevailed, but more readily in those who are of a scrofulous disposition, or in other words, who are predisposed to irritation of the lymphatic system.

170. Cartilaginous, osseous, and calcareous depositions, appear to be produced in the same manner as tubercles, and the same applies to melanosis, scirrhus, and various other morbid growths.

171. The term *phthisis pulmonalis* only expresses the disorganisation which is the *product* of parenchyma, and therefore is a bad term for the disease. *Chronic pneumonia* is a better word specifying the tissue in which the inflammation commenced.

We need hardly say that these opinions have been disputed. We must refer those interested in the doctrines of Broussais to the early numbers of the *Med. Chir. Review*, if they desire to obtain a superficial knowledge not only of his principles but of his other writings which are very numerous, for he promulgated his theories *vi et armis*. Deeper students must go to the fountain head and consult the original writings of the master.

OBSERVATIONS ON SOME OF THE WAYS FEVER MAY COMMENCE; WITH A FEW CURSORY REMARKS ON ITS TREATMENT AT THE PRESENT DAY. (a)

BY HENRY KENNEDY, A.B., M.B.,

Physician to the Whitworth Hospital, and the Drumcondra and Simpson's Hospital, &c., &c.

ON a late occasion you, Mr. President, strongly enforced the importance of the study of physiology, for the sure advancing of surgery; in which medicine also might have been included. For I believe physiology to be the only basis on which our art can be raised to the rank of an exact science; and it seems to me that medical diseases demand a greater knowledge of physiology than does even surgery; for in the latter a vast deal can be brought under the senses of sight and touch, whilst in the former quite as much is entirely hidden from us. It is not, however, on this branch of scientific medicine I would now speak; but on one which has a most important practical bearing, on those diseases at least with which the physician has more particularly to deal—I mean the knowledge of the natural history of disease; the course, in fact, that any given case will run, when left entirely to itself. I believe that physicians are able, precisely in proportion to the amount of this kind of knowledge they possess; whilst, on the other hand, a want of it constantly leads to erroneous inferences and conclusions. Our medicines are credited with effects to which they are not entitled; for the case would have run the same course without them. How many medicines have been vaunted as a cure for fevers? And yet, except one or two, such as quinine or arsenic, we have really one on which absolute reliance can be placed.

Thoughts like these, and the subject could be largely extended, come into the mind when we speak more particularly of fever. Here the origin, course, and termination of the disease are really almost endless. I have heard fever described as the study of a life, and I believe he will be a fortunate man if, even then, he has grasped the entire subject. That its natural history, even on points of common occurrence, is at times liable to be misunderstood, I can scarcely doubt. I might instance hæmorrhages whether from the head, chest, or abdomen, which are apt to be misinterpreted; or that remarkable event, the crisis, the occurrence of which some even at the present day are inclined to question. On such points as these, and it is beyond question they present themselves as parts of the natural history of the disease, we cannot be too familiar; and did time permit there are many other points equally worthy of attention.

I have just glanced at the subject in this way because it enables me to introduce here the shortest sketch of some cases of fever recently under my care, and which began in a way I was not prepared for; and which I now proceed to do.

CASE I.—A gentleman, æt. 30, came to my house to consult me for neuralgia of the face, which for some nights previously had entirely deprived him of sleep. The pain was clearly of a very severe character, and wonderfully periodic in its attack; for it began each evening exactly at seven o'clock, and lasted till morning. I saw nothing which specially attracted my notice at this time, except that his tongue had something about it which betokened more than an ordinary attack of neuralgia; there was, however, no increase of temperature, nor was the pulse quickened. The bowels were confined. Two days subsequently I was sent for to see him, and found he was complaining much of general *malaise;* whilst the neuralgia, for which quinine had been ordered, though not given, had lessened in severity. It is enough to say of this case that it cropped, in the slowest possible way, into typhoid fever. I say slowest, for it was literally ten days before I could name the disease, and then only from the presence of spots, of which there were two distinct crops. This patient, when now about sixteen days ill, got a severe attack of diphtheria; and I may men-

(a) Read before the Surgical Society of Ireland, Feb. 1, 1878. The discussion will be found at page 172.

tion in passing that, in my experience, this has not been a fatal complication of fever.

Case II.—Mrs. D., an Englishwoman, æt. 39, was attacked with severe pain in the left ovary, to which she had been subject, off and on, for the last five years. I was sent for to see her whilst suffering from this pain, which seemed to be very severe, and had gone on now the greater part of two days. With it there was some fever, and her aspect at once caught my attention, being like that of a person under the influence of strong drink. She was still struggling to go about. It is enough to say this case ran into fever of a very severe, but anomalous kind. It was more typhus than anything else, the brain being deeply engaged, and there being mottling of the surface without any distinct rash. On the other hand, there was very severe diarrhœa, the motions, when the fever was at its height, being passed in bed. This case too got a bad attack of diphtheria, after being fourteen days ill. Had it not been that some external swelling showed itself, I should very probably have overlooked this occurrence; for I need scarcely say that fever of this type blunts the sensibilities of the frame in a very remarkable way; as regards not only the throat, but other parts of the body. It is owing to this, in fact, that chest complications are so apt to be overlooked, and so often prove fatal. It is to be noted of this case that stimulants did not agree with her at all; and I mention the fact because there seems to be a very general impression abroad that wine or other stimulant is a *sine qua non* in the treatment of fever. It is not so; and though I cannot say in what proportion the cases occur in which stimulants are not needed, I have not the slightest doubt of the fact. My note-book contains a very considerable number of cases of this kind.

Case III.—A man, near 50 years of age, employed in a business, sent for me, as he had got a severe attack of sciatica. He had been suffering for ten days, and attributed the attack to sitting on an outside car during heavy rain; a very ready way, it must be allowed, to get such a disease. I do not know that I ever saw suffering of greater intensity than this patient exhibited. He was evidently a man of the most resolute will, and bore his suffering with heroic courage. Yet in the attacks of pain he writhed in agony, and would then break out in cold perspiration. The suffering was referred to the back of the right hip, and a little down the back of the same thigh. Though his tongue was slightly furred there was not a trace of fever on him. He was reported to be a healthy man previous to this attack, and was certainly temperate. Mustard poultices had been applied so frequently to the hip that when I first saw him I found the cuticle had been entirely removed, leaving a large surface perfectly raw. The remedies used, and they included opium and morphia in every shape and mode of administration, seemed to be entirely useless. The suffering persisted as bad, if not worse, than at first, and as a last resource I thought well of trying some leeches to the painful part. This was done, and was the first measure which afforded any relief. The patient asked for them to be repeated the following day, and his wish was complied with, and was followed by still more relief. The third day from the application of the leeches, and the sixth from my first seeing him, I found the pain had lessened much. But his wife told me that morning, for the first time, he had refused his breakfast, as his stomach was sickish. I observed now that his pulse had risen a little, and his look was depressed. He spoke too despondingly of himself. All pain had disappeared. But if it had it was only to be followed by steadily advancing symptoms of fever of a very severe type. The stomach became very irritable, great tympanitis showed itself, and the mind became heavy, and finally coma set in; and in this way the patient sunk. When the fever was fully established Dr. Cruise saw the case.

For the result of this case I confess I was quite unprepared. That one of sciatica, no matter how severe, should end so was, to say the least of it, strange. On thinking over the entire case it seems to me possible that the fever owed its origin to the leech bites, which it will be recollected were on a very raw surface. That the patient had no fever on him when I saw him first is certain, and I have somewhere read of the bites of leeches being followed, in some peculiar constitutions, by very untoward results; just as has happened after the wound of venesection, or indeed any other wound. Looked at in this light there was no necessary connections in this case between the neuralgia and the fever; still I have thought the case worth relating, as showing under what an unusual combination of circumstances a fatal fever may develope itself.

The three cases given occurred, as I have already stated, within a very short period of each other, and beginning with a local neuralgia, could not fail to attract my notice. General pains are known to be very common. But cases like those described I take to be very rare, and the more worthy of being kept in remembrance. A second way in which fever, especially typhoid, may begin, is as bronchitis, and that this state may be considered the sole disease present I know to be a fact. I have made the mistake myself, and have been called in consultation, more than once, to treat what was described to me as a case of severe bronchitis, but which proved, in the sequel, to be typhoid fever: the patient really presenting nothing more, for several days, than the symptoms of acute bronchitis. Neither did the thermometer in these cases give any such help as would establish the diagnosis. I may state too in connection with this class that I have seen cases where the signs of bronchitis all disappeared, to be followed by all the symptoms of typhoid fever, including the spots and diarrhœa. Probably a case of this kind, given very briefly, may not here be out of place.

Case IV.—Mrs. K., æt. 26, her skin very fine, and of a high colour, was admitted to hospital, labouring under well-marked symptoms of bronchitis, spread over each lung. She complained only of her chest and cough, and the fever was slight. In the course of a week she was much better, and seemed to be nearly well. It was now observed, however, that the fever began to rise again; and in the course of two days the thermometer ranged at 102, and still later reached 105. With this change came all the signs of typhoid fever, through which the patient passed, and as she got well of this, the bronchitis again appeared. Now, in cases of this type, I take it that the chest affection is but a part of the more general typhoid state, even though it preceded by days the symptoms referable to the abdomen. No one who has studied typhoid fever can for a moment suppose that all its symptoms are due to what occurs in the abdomen. The morbid changes found here are quite too varying to allow of such an idea. It has even proved fatal where the amount of disease found has been of the very slightest, and cases again are by no means uncommon where far more disease has been found in the colon than the ilium. Bronchitis, we know, is a very frequent sequel of typhoid fever after the abdominal symptoms have continued some time; but what I wish to direct attention to is the fact that bronchitis may precede the abdominal symptoms.

The last way in which fever may be ushered in, so as to lead to an error in diagnosis, and of which I would speak here, is by the occurrence of acute rheumatism. Not, let it be observed, those general pains which usher in so many acute affections, but by regular swelled and very painful joints. Till recently, I thought this was an observation of my own; but in one of the volumes of Hospital Reports, just issued in London, I find the same fact has been witnessed, and is specially stated. This is a state of things which might very readily throw us off our guard, and is the more to be remembered. Speaking of acute rheumatism in connection with fever, I may observe in passing that I have seen it occur when typhus was at its very height, and also in some cases of scarlatina, whilst the rash was still fully developed.

Before concluding these observations, I would wish to say a few words on the subject of the treatment of fevers

generally, and which have, as it were, forced themselves on my notice by the publications of the present day. The first is the dictum that fevers, whether typhus or typhoid, of which alone I am now speaking, must run their course, and that all the physician can do is to watch, tend, and feed them. Now this teaching—I care not by what authority it is supported—I distinctly challenge. Such experience as I have had, and it has been tolerably extensive, is strictly opposed to it. Can it be, I ask myself, that the physician is not to treat the fever otherwise? He knows that a morbid process, of an inflammatory kind, is going on, let us suppose, in the lower portion of the ilium, and that the strong tendency of this process is to run into ulceration, and other serious consequences; and that when these ulcers once occur, recovery must, at the very best, be very slow, and, it may be, uncertain in the result. Possessed of this positive knowledge, I ask, Is this state to be met by poultices, turpentine stupes, and a mild diet? Is it likely to be conquered by such treatment? For my part, I must answer by a direct negative. When we have inflammation to treat in any other part of our frames, are we satisfied so to leave it? Yet this is what must be called the fashionable treatment of the day; and I could name a number of authors who recommend it, and who maintain that fever can only be treated on this plan. I am quite ready to grant that in many cases Nature can and does restore health, even with this feeble treatment. But I also know there are many where the disease progresses very much farther, and if it be not stopped, will surely lead to disastrous results; and for any physician to stand by, and only use such means as have already been stated, appears to me to be worse than foolish. For I maintain that every effort should be made to check the disease, but that this is not done by the plan I question. To tend, and feed, and stimulate, is one thing, but to treat disease is quite another; and it has always appeared to me that the way to consider this important subject is by saying that the physician treats and, with the assistance of Nature, cures disease. To enter farther into this question here would be quite foreign to my present purpose. But I have thought well of saying so much about it, as I firmly believe the general teaching of the day to be a grave mistake.

With only one other point shall I now trespass on the meeting, and it has reference to the mode of feeding fevers at present in use. That fevers are to be fed may be freely granted; but I believe that in many cases this is overdone, and to the injury of the patient. There is such a desire to keep up the strength, as the phrase is, that food is apt to be given beyond the powers of the system to digest, and nothing but bad consequences can ensue. Even with such an article as milk I have reason to believe mistakes are frequently made. I have known a patient, in typhoid fever, getting five quarts of milk in the twenty-four hours—the parties treating the patient thinking they could not give too much of it—and great was their surprise when it was recommended to lower it to three pints, and so give Nature some chance of setting matters to rights; and so of other cases. I may take this opportunity, too, of stating that there is very much less risk when stimulants happen to be overdone than there is when food, such as milk, is given too freely. The effects of the former are transient, in comparison with those of the latter. Most, however, look upon this point in a different light. Speaking again of milk as a suitable food for fever, I observe a late writer in the *Practitioner* recommends it as the only thing needed, though, he adds, that at times eggs may be added. Now I cannot but think there must be some mistake here; for it is beyond question that a good many individuals, and more particularly adults, do not bear milk at all, and other food must be used. How any one can make a statement, such as I have described, is hard to understand. In the last place, I would notice a paper, also in the *Practitioner*, and very recently published by an American physician, who recommends, and in perfect soberness too, that solid food is to be given in typhoid fever, and if the patient cannot take it, he is to be forced! If all experience, to say nothing of common sense, can be farther outraged, I am at a loss to understand how it is to be done.

These, I feel, are very desultory remarks; but believing that one and all have a practical bearing, I have ventured to bring them forward.

ON SYPHILIS AS IT AFFECTS THE BRAIN AND NERVOUS SYSTEM.

By THOMAS STRETCH-DOWSE, M.D., F.R.C.P. Edin.,

Late Physician-Superintendent to the Central London Sick Asylum, Highgate; Physician to the North London Hospital for Consumption and Diseases of the Chest.

(*Continued from page* 123.)

DIAGNOSIS.

It must be admitted that we are powerless to combat disease successfully unless we have a thorough and complete insight into its mysterious and marvellous workings, and it must be apparent that want of success in treatment is in many instances really due to this lack of insight.

The faculty of observation is one thing, but the power of using this faculty aright, is another.

When we take into consideration the whole composite human individual, with his intellectual and physical attributes and peculiarities, the complex structure of his organism, and the laws and powers which regulate his being, we begin to experience a sense of conscious inferiority, relative especially to what has been—and is now being—done even by the most thoughtful scientific observers to unravel the relationship which exists between life and health, and to bring a more direct influence to bear upon the connecting links between disease and death.

It is then only we begin to see the huge task which lies in the path of the physician, and to comprehend the right and sure road by which he can arrive at a complete and thorough investigation of subjective, not less than objective, morbid processes.

If we do not, however, make ourselves acquainted with the true position of human science, which is the true philosophy of Nature herself, we shall never be able to grapple with the obscure signs and symptoms which are the evidences of the disruption and disorganisation of her normal processes.

We must bring the force of intellect to bear upon every point—not one single faculty or function must be unheeded; for want of knowledge in the least minutiæ has not unfrequently reversed the balance between life and death. Whilst, on the other hand, even a due appreciation and a sure judgment has sometimes failed, until the mind has been quickened to the consideration of what, under ordinary circumstances, might have been thought to be matters of little moment.

We sometimes find physicians of eminence who will not allow the claim of men devoted to natural science—mere physicists as they are called—to advance an opinion upon a subject which has a direct medical bearing.

To speculate upon an opinion is an act of the most egregious and unpardonable folly. To be dogmatic and self-assertive without due reason, is illogical and unjustifiable. Yet this tendency does exist even in the minds of the profoundest thinkers and philosophers, and sometimes proves the greatest obstacle to the spread of truth, and the most fruitful source of error.

For the correct diagnosis of diseases of the nervous system, and for the employment of rational remedies in their cure, we have at our command materials of potential value. As the stethoscope is to the chest, so is the ophthalmoscope to the brain, and the one is certainly of no more special value than the other. Disease of the chest can be elucidated without the stethoscope, and disease of the brain without the ophthalmoscope; yet they are aids to a perfect diagnosis, which a careful observer would not think of setting aside.

One cannot consider this branch of the field of medicine without feeling how very greatly indebted the profession is to the valuable and extensive labours of Hughlings-Jackson, Clifford, Allbutt, Hutchinson, and Gowers. As the eye is one of the most sensitive tests of pathological processes, the knowledge of its reaction in disease of the brain and nervous system will certainly be found of considerable value.

Neuro-retinitis is a common accompaniment of syphilis, and may perhaps be a characteristic feature.

Choroiditis is an almost undoubted indication of old standing syphilis.

Optic atrophy is the least important of all the ocular changes as a sign of syphilis, and should be relied upon merely as an aid to other diagnostic evidence.

In *La France Médical* of March 27th, 1875, M. Bouchat, who has given especial attention to medical ophthalmoscopy and cerebroscopy, lays down the following four laws in reference to the formation of intra-ocular lesions depending on diseases of the brain, spinal marrow, and meninges. "1. Whenever the circulation is obstructed, in the cranium or in the sinuses or meningeal veins, in consequence of compression through distension of ventricles distended by serosity, or any other cause, an arrest of the venous circulation occurs which produces swelling, hyperæmia, and œdema of the papilla, varicosity of the veins, and sometimes hæmorrhage into the eye. 2. When a tumour with encephalitis, or partial encephalitis, is present, a descending phlegmasia occurs which brings on sclerosis of the optic nerve, exudations which imprison the papilla, and eventually produce atrophy. 3. If it be the spinal marrow which is diseased by anterior or posterior sclerosis, since that organ, on account of its relation with the great sympathetic nerve, acts on the eye, papillary hyperæmia of the eye results, which in time brings on atrophy. This is what is seen in locomotor ataxy. 4. Finally, in all diathesis, and in poisonings when the whole organism suffers, the eye suffers like the rest of the body, and certain forms of neuritis or choroiditis result."

Again, as in percussing the chest we ascertain its resonant power, so in percussing the skull and finding out the initial vibratory radiation of sound by the tuning fork, we discover the existence of subjective morbid phenomena, which give outlines of no small importance to complete the clinical picture.

Then we have the faradaic and continuous currents, the dynamometer and the dynamograph, each of which has its own especial uses.

In dealing with many forms of disease of the brain and nervous system, the greatest care is often required to lead us to a true and successful issue; there is not one tithe part of the dissimulation of diseased state which we constantly hear so much talk about.

There are thousands and tens of thousands of the occupants of our globe suffering from absolute disease of the brain and nervous system, who are set down by the world at large as ill-conditioned, morose, disagreable creatures, hysterical, irritable, discontented; in fact, anything but what they ought to be. Their friends will say the most extravagant things—that they cannot be responsible, they cannot be in their right minds, and this last statement is in a measure justified.

What is the condition of the brain of the true dipsomaniac, who has less power than a child to resist the craving for drink? yet in all other respects the character and life of the individual may be unexceptionable.

Or the kleptomaniac, who cannot resist the propensity to steal; the hystero-maniac, who believes that her legs are powerless, that she is suffering from some grave disease which will cause her death; the melancholic, who has an idea that he is doomed to perdition? What is it that induces the loftiest-minded girl, whose life has been both by physical and mental training that of absolute purity, to suddenly become possessed with the idea that she has committed some dreadful deed which cannot be pardoned by God or man, and she either attempts at or commits suicide?

Then, again, we often find the creature of mere impulse who suddenly performs the most extravagant acts without rhyme or reason, and who is quite unable to explain the motive for so acting. This condition is invariably associated with epilepsy, and the subject is as much an epileptic as any who have confirmed epileptic seizures.

The time has passed (thanks to the recent researches of scientific investigation) for us to look upon these conditions as partaking of a morbid spiritualistic or psychical origin. We now know full well that there is a material cause at work which gives rise to the arrest of function, either secretive or excretive, partial or complete, and undermining it may be many of our special mental attributes, and so disturbs the harmony which normally exists between the higher and most complex functions, of which volition, intellect, and reason are the human manifestations. The brain and nervous system being the material congeners of these perturbed states, it scarcely requires reflection to assure ourselves of the truth of these remarks. For instance, a poisoned blood will produce them, having its origin from within the body due to an arrest of the secretory normal action of the liver, the kidneys, or the skin; or from without, by the introduction of septic or poisonous matter. A vaso-motor paresis of the vessels of the kidney will produce acute madness in the twinkling of an eye, lasting, it may be, for ten minutes or twenty-four hours. The same condition of the vessels of the brain will produce a paralysis more or less profound, or it may affect only the depressing or stimulating nerves which govern the rythmical action of the heart, lungs, stomach, intestines, or involuntary muscles generally or locally, causing an irregular pulse and cardiac depression, paroxysms of difficult breathing and asthma, indigestion, biliousness, constipation, or diarrhœa; and when nutrition becomes seriously impaired, then commences those organic changes with which pathology has made us so familiar.

Now, of all inhabiting poisons, there is not one which plays so important a part in upsetting those primary laws which govern the stability of the nervous system as syphilis. Paracelsus was familiar with this when he stated that syphilis takes in every man the character of that disease to which he is inclined by hereditary or other predisposition. There can be no doubt that gout plays a very important part as the *fons et origo* of these morbid phenomena just enumerated, but compared with syphilis it is as nothing. The universality of syphilis and the constitutional changes which it gives rise to, both in the acquired and the hereditary form, as well in derangement of mind as in defects of body, are, I am fully convinced, only just beginning to receive anything like their due share of attention.

It is only within a very few years that syphilis has been considered a "disease proper" for the physician; and, what is more anomalous still is this, that until recent investigations, physicians have sometimes discarded even with indifference, signs and symptoms which we now know to be essentially syphilitic. We have only just commenced to tread firmly upon this forbidden ground, which yet awaits exploration. I would remark, however, that a heavy responsibility rests upon the shoulders of any medical man who neglects to enforce upon his patients the absolute necessity of a mercurial course in the primary stage of syphilis, for an incomplete hesitating treatment of external syphilis specially predisposes to subsequent affections of the nervous system.

We have noted in writing of the pathology of syphilis (see page 168, last vol.) that it can affect the brain, the spinal cord, the nerves and their membranes in several ways:—

1st. By pressure from gummatous outgrowths of the cranial bones, or from inflammation of the endosteal lining through which the nerves pass in making their exit from the skull.

2nd. By pressure from growths in the membranes, most

frequently of the dura mater, rarely of the pia mater, and still more rarely of the arachnoid membrane.

3rd. Quite exceptionally by growths commencing in the brain substance in the tunica adventitia of the vessels.

4th. By vascular changes commencing in the inner wall of the vessels leading to mal-nutrition, exudations, hæmorrhages, softening, atrophy, and thrombosis.

5th. By changes in the sympathetic nerve ganglia most frequently associated with protoplasmic and albumenoid visceral changes. It is at the commencement of these that we find functional nerve troubles to arise.

6th. By changes in the vaso-motor and intrinsic ganglia and trophic nerve plexuses of the heart, spleen, and uterus (associated with both acquired and hereditary syphilis, but more particularly with the latter).

We shall see as we proceed how these varying abnormalities are to be recognised.

There are two prime factors which tend to induce syphilis to expend itself upon the brain and nervous system. The first of these, and, perhaps, the most important, is an unstable condition of these parts from hereditary predisposition.

The second is due to an instability which is the result of previous inflammatory change, in its origin, either idiopathic or traumatic (see Case I., p. 254, vol. i.), or from molecular derangement followed by want of due selective nutritive capacity in the nerve or connective tissue-cells, by which their tonicity is impaired. Such a condition as this arises from exhaustive and debilitating diseases, the exanthema for example, but more particularly in shattered constitutions from the effects of drink and exposure, and, in fact, from excesses of all kind. I have clearly traced a cerebral syphilis where the exciting cause has been venereal excesses, over-study, mental anxiety, worry, and even fright.

Lancereaux states that more cases of cerebral syphilis occur among the learned professions than among the lower classes, which may be due to the demand made upon them for great brain exertion ; and, again, we must not forget that special relapses of constitutional syphilis, under some conditions, favours the outbreak of nerve syphilis.

I have heard it stated that it is impossible to distinguish a hemiplegia, the result of a syphilitic lesion, from a hemiplegia, the result of any other tumour of the brain. But if two disconnected paralyses give evidence of two cerebral growths, then syphilis may be expected ; and such a condition of brain as a cause of paralysis could scarcely be doubted if the skull was carious, and nodes were to be found upon its surface, or upon the extensor surfaces of the long bones. I think there are few medical men who doubt these facts. But in dealing with syphilis in any of its forms, no matter whether of nerve, muscle, or of bone, experience has taught me, as it has taught many others, that definition, symmetry, and uniformity, are by no means ts especial attributes in any of its stages ; in fact, its manifestations may be symmetrical, or they may not.

Mr. Hutchinson, with all his experience, speaks of syphilis as a "wizard" ; but, as Dryden says, "the wily wizard must be caught" ; and doubtless, in time, he will be secure enough, if hunted down by men of Mr. Hutchinson's sagacity. At present, however—and we must deal with facts as they stand—it is the magician-like practices of syphilis which give to its study an especial charm, and which undoubtedly helps us materially to realise its existence.

If vagueness, evanescence, and vagrancy, are the characteristics of syphilis when contrasted with other diseases, it behoves us to deal with it in such a manner, and under such circumstances as would appear out of place when applied to other diseased states. Then let it be clearly understood that among the protean signs of syphilis of the nervous system, are its instability of character, its tendency to spontaneous resolution, and its disposition to necrobiotic change, when subjected to the action of mercury.

There is no other tumour of the brain or its membranes, or of the spinal cord or its membranes, of which the same conditions may be affirmed in anything like the same degree ; and there are only three factors of paralysis—if we exclude reflex and hysterical paralysis—namely, Embolism, Thrombosis, and Hæmorrhage, with which syphilis can be confounded with other processes ; but the onset of these is usually sudden and complete, whereas syphilis in its working is slow, alternately progressive and retrogressive.

It must not be forgotten that apoplexies do occur in association with gumma, and with arterial changes ; but there are always prodromata which the practised senses can detect long before this event arrives. And if we have not positive evidence of syphilis about our patients we are not to conclude from this that their disease has no connection with syphilis, neither can we in all cases be guided by their own statements in this respect, and the reason for this is obvious enough.

The differences above referred to can now be more fully considered, and I hope that some essential points may receive elucidation.

Pressure on the Brain and Cord from Endosteal Gumma.

The following two cases will show in a manner at once definite and comprehensive, the signs and symptoms by which these forms of invasion may be diagnosed.

Case XIV.—*Endosteal Gumma of Internal and Exterior Table of the Skull in the Right Posterior part of Supero-Antero-Parietal Area exercising pressure upon the Convolutions bounding the upper extremity of the Fissure of Rolando.—Ferrier's Centres for Complex Movements of the Arms and Legs.—Recovery.*

T. M., an officer, æt. 60, came under my care in the month of April, 1877. When young, he fell heavily whilst riding in India, and besides fracturing the right collar-bone, he struck the right side of his head. He was for a while unconscious, but eventually recovered, and enjoyed excellent health. At the age of 43 he contracted syphilis in a very severe form, which so depressed his spirits and unfitted him for his duties, that he was compelled to resign his commission. After a considerable time he improved greatly, and all went well enough with him for many years. At the age of 59, in the middle of a hot summer's day, he became faint and partially unconscious. From this time he complained of great pain in the head, coming on at a certain time every night, and continuing until a certain hour in the morning ; it was more or less circumscribed and confined to the parietal eminence, which was the focus of intensity, and from which the pain radiated. When pressure was exercised upon this central spot the pain was increased. It was of a dull, aching, and (at times) throbbing character. It would continue for a few days or even weeks, and then leave him for a time, only to return with increased severity.

When I first saw him he was pale, weak, and, in fact, as he said, thoroughly worn out with pain and sleepless nights. His appetite was bad and his digestion faulty. The ophthalmoscope did not show any retinal change.

During the paroxysm of pain the intellect was obscure, the memory weak, and the frame of mind variable. There was a very slight pseudo-paresis of the left side of the face, arm, and leg.

His attention was first drawn to the failure of power in the arm, when he was in the act of raising a glass to his mouth ; his grasp became relaxed, and the glass fell.

Sensation was less affected than motion, there were no formications, and only slight subjective sense of heaviness.

The paralysis was evanescent, and at times the leg would feel weaker than the arm, at other times the arm would feel weaker than the leg.

Upon examining the head I found a semi-elastic circumscribed swelling over the parietal eminence, and concluded that in addition there was caries of the skull, and an endosteal swelling similar to that visible on the outer surface, but from the manner in which this patient improved under the mercurial treatment, with enforced nutritious diet, I am led to the belief that an internal as

well as an external gumma existed, and that there was merely an inflammatory hyperplasia of the bone structure.

In casting our eye over the signs and symptoms here very briefly enumerated, we find a ground for diagnosis of the utmost practical value. There is the dual history of injury to the head (a weak spot in the man's physical being), and of syphilitic infection. It must be observed that beyond fainting there were no fits, no inco-ordinate convulsive movements, or sudden jerking of the extremities; no neuralgic pains affecting the fifth-spinal accessory, or cervico-brachial nerves; that the headache was of a wearing dull character, unaccompanied by any great increase of nocturnal temperature; that it was not diffuse, but radiated from a given centre, and that this centre was of higher temperature than its surroundings; that the paralyses were confined to mere weakness, and a sense of heaviness about the limbs, and that it was evanescent.

Judging from signs and symptoms, and from pathological experience, I conclude that the dura mater proper, the other membranes, or the surface of the brain, did not participate in this syphilitic inflammation; but that pressure only to a slight extent, and evenly exerted, produced the paretic state.

CASE XV.—*Intermittent Paralysis of the Lower Limbs of motion only, presumably from growth of a gummatous nature proceeding from the* 11*th or* 12*th Dorsal Vertebra, and involving the Anterior Columns of the Spinal Cord, the Membranes, and Nerves, producing severe Reflex and Automatic Movements* (Spinal Epilepsy)—*Recovery.*

M. A., æt. 43, was admitted under my care in January, 1875. There was undeniable evidence of syphilis contracted when she was 37 years of age, but no nerve symptoms were noticed until she was nearly 40. There was no neurotic history, and her general health was usually good.

About six months previous to disordered nerve-manifestations, she suffered from an attack of small-pox, and after this she was weak, and never regained her strength completely. She complained of dull aching pain in the spine, but especially about the 12th dorsal vertebra. For a time it was fixed to this spot, but became always worse at night, extending up the back between the shoulders. In a little while she was seized with cramp in the muscles of the thighs, associated with tonic spasms of the lower limbs sometimes brought on by sudden movement. There was marked absence of the signs of a local myelitis of the anterior horns of grey matter, such as formications, tingling, intrinsic muscular movements, cramps, and subjective sensations of burning, coldness, &c. The sphincters were never affected. The urine was of acid reaction and of normal gravity. At times there was a feeling as of a cord tied round the belly, but this was very variable. The electro-cutaneous and muscular response was either normal or exalted. Stohrer's induced current gave the following results:—

Cutaneous Sensibility.

Feet - - -	20 cells
Flexor surface of legs -	12 ,,
,, ,, thigh -	10 ,,

Over Spinal Cord.

Region.	Time of Response.	No. of Cells.
2nd Dorsal Spine	- 4 sec. -	12
4th ,,	- 6 ,, -	,,
6th ,,	- 1½ ,, -	,,
10th ,,	- 3 ,, -	,,
2nd Lumbar Spine	- 3 ,, -	,,

There was no muscular response to anything under 20 cells.

Now, concerning the actual paralysis; it came on in the following manner:—

She was wakened out of her sleep during the night by the violent startings of the lower limbs, and on the following morning found that she was unable to stand without support, or to move the lower limbs freely while lying upon her back.

During the day, as the extremities became warm, her condition improved, and she could shuffle along from one part of the room to the other. But sometimes she would fall down suddenly as if shot, and said that her legs completely gave way under her.

It must be remembered that none of the signs of postero or even unilateral pressure were observable. At one time motor power was almost completely lost, but sensation and sensibility remained normal.

Taking these signs to guide me I came to the conclusion that my patient was suffering from pressure upon the cord, the membranes, and the efferent nerves, which must have been caused by one of three conditions.

1st. By an abscess due to necrosis of the bodies of the vertebræ. (there was no spinal distortion)

2nd. By some low chronic form of inflammation of the membranes involving the anterior columns.

3rd. By some growth.

The two former supposed causes I decided were inadmissible from the objective and subjective signs and symptoms, both direct and indirect. In fact, I felt sure that the third condition was the most probable—that some tumour was exercising pressure. Cancer, tubercle, and possibly osteo sarcoma, were at once set aside, and it was considered that a gumma was in fact the nature of the growth in question. The treatment bore out the diagnosis. Twelve leeches were applied, and then the painful spot, as well as the whole spine, was treated by the application of a strong hot solution of chloral.

Morphia injections were used night and morning, and the ordinary blue pill, with iodide of potassium, was given freely. No perceptible change in the paralysis was observable for three weeks, but at the end of this time all her troubles seemed to be relieved as if by magic, and at the end of a month nothing but weakness remained as testamentary evidence of a very grave and serious malady. Galvanism and cold douches helped to perfect the cure, and she left the building in the month of March apparently well.

She then went to service, and kept in good health for two months, when she again came under my care with precisely similar symptoms. She said her back became painful, and then the spasms and paralysis returned in the same way as before. A precisely similar treatment was adopted, and her recovery was, of the two, more rapid. She followed my advice, and continued to take the iodide of potassium for many months. I saw her last November, and she told me she has had no return of the paralysis whatever.

I do not think that it requires either much skill or great care to diagnose satisfactorily the nature of the disease we here meet with. Its precise local manifestation, as well as the local functional disturbance of the spinal cord, its somewhat rapid advent and hasty departure, with a well-marked syphilitic history, are proofs conclusive.

These are two cases which I have taken from my note-book especially to illustrate a by no means uncommon form of paralysis by pressure of a gummatous growth; and these growths may arise and make considerable advance before their presence is detected, when quite suddenly we have apparently very serious nerve lesions produced, and not unfrequently has hæmorrhage or thrombosis been diagnosed as their cause when these conditions have not existed.

Under these circumstances local blood-letting and mercurialism are the appropriate remedies, no matter what is the apparent constitutional state of the patient, as long as he is carefully fed and well-nourished. Arterial tension and vaso-motor influences can be treated by strychnine, ergot, and digitalis, upon strictly physiological principles, when the disease has become so chronic that iodide of potassium and mercury are no longer able to prove their potency, and the patient's withered limbs stands forth as spectres of clinical reclamation.

Clinical Records.

RIGHT LOBAR PNEUMONIA IN A CHILD. WITH REMARKS.

Under the care of H. CRIPPS LAWRENCE, L.R.C.P. Lond. &c.,
Hon. Phys. North-West London Dispensary for Sick Children.

M. A. R., æt. 7 years, was first seen on December 28, 1877, and found to be ill with catarrh and disordered digestive functions, accompanied by the excretion of light-coloured offensive fæces, which were scybalous, mixed with slimy mucus, and streaked with blood. The little girl had been ailing a few days before my visit. Her temperature and respiration was normal, but the pulse somewhat accelerated, and the tongue coated with a creamy white fur. A mixture containing small doses of castor-oil and opium speedily relieved her, and on January 3rd, 1878, she was practically convalescent, and able to be up on the next day. On January 5th, however, she was dressed, without advice, at an early hour, and allowed to be up and about for several hours. During this liberty, she partook freely of food, including thickly-buttered bread. At night she became feverish, and coughed, and complained of severe pain in the right hypochondrium. On January 6, she was seen, during my absence, by my friend Dr. Dawson Nesbitt, who detected "a creak," probably a pleural friction sound at the base of the right lung.

On January 7, 1878, I found her in bed, with flushed face, pungent heat of skin, extreme tenderness over the right hypochondrium, short hacking cough, temp. 104; pulse, 120-140; resp. 48-52. Tongue very coated with a thick white fur. Bowels confined. There was evidence of a slight pleuritic effusion, and commencing congestion at the lower third of the right lung. She was ordered to take every four hours a saline mixture, with chlorate of potass and small doses of ipecacuanhâ wine; also ℥j ol. ricini statim, which latter produced five copious semi-solid white evacuations. Her diet was to consist of a teacupful of milk-food, alternating with some animal broth every three hours, and she was to be sponged with tepid vinegar and water every six hours; a light lin seed cataplasm being renewed every four hours around the whole of the right side of the chest.

Her temperature on the 8th and 9th of January, varied between 104°F. to 102°F., with correspondingly accelerated pulse and respiration; but on the afternoon of January 8th, the temp. was 104·2°F., with resp. 52; pulse 140, and there were present great restlessness, with increase of cough, scattered dulness over various parts of the right side of the chest anteriorly, with bronchial respiration, while posteriorly the level of dulness had extended slightly upwards, and tubular respiration, with increased vocal vibration and resonance, were evident by comparison of the left side. There was no displacement of the apex of the heart. The left side was clear. I now ordered half grain doses of quinine, with ℥v. of dilute hydrochloric acid every four hours. In other respects, the previous details in the treatment continued. On January 10th, I found the little patient had passed a better night. Temp. 101°; resp. 48; pulse 88; in the morning, there was no extension of the pneumonia. At 4.30 p.m. of the same day, I had the advantage of a consultation with Dr. Andrew Clark, who confirmed the diagnosis, and approved the treatment. There was, however, now diminished movement on the left side, and a scattered hyperæmia affected the surface of the left lung.

We concluded that resolution was imminent, and that the temperature would continue to fall. On the 11th, the morning temperature was 100° F., and in the evening 99° F., and on the 12th 98·4°F. Resolution occurred, therefore, on the fifth day, practically earlier.

Dr. A. Clark advocated, should the cough become very irritating, as the sputa were evidently highly tenacious, that the quinine should be given in effervescence, which suggestion I followed with advantage a few days after his visit.

Previous History.—M. A. R., was vaccinated in infancy, when three years old; had a laryngeal cough with fever, which her mother was informed was croup; when four years old, she was ill for about six weeks with a severe gastro-intestinal attack, accompanied by obstruction in the cæcum, at which time she was first seen by Dr. Andrew Clark.

Remarks.—Lobar pneumonia is generally considered to run a cyclycal course, but practically it may be said that clinical varieties of pneumonia exist, the variation evidencing itself both in the etiology as well in the progress and course of the disease. I have ventured to record the above case, because it appears to represent a clinical variety of lobar pneumonia. Two well-known factors were present as predisposing causes, a subacute gastro-intestinal attack preceding the pneumonia by a few days; and secondly, the patient was one of four members of the family all occupying one room, ill-kept, and badly ventilated. During the same time, both the mother and a little brother, aged four years, were attacked with gastric disturbance and fever; the boy having subacute scattered congestion of the lungs, which ran a rapid and irregular course. One is apt in acknowledging the cyclycal type of lobar pneumonia to accept the tenet that good hygiene and good food will, in the majority of cases, result in resolution of the pneumonia on a certain day, but it is also possible that nature may be aided by art to abridge the term; and I believe that in the case I have recorded, quinine expedited the resolution. This view was maintained by Revillout (*Gaz. des Hop.* 1871, 273) when criticising the teaching of Jacoud ("Traité de Pathologie Interné," Paris, 1871, ii). See article Pneumonia, New S. S. Bienninal Retrospect, 1871-72.

THE NEW HOTEL DIEU, PARIS.

Asthma.—Treatment by Iodide of Ethyl.

Under the care of Professor GERMAIN SEE.

I HAVE employed this agent in five cases of asthma, and the attacks have been arrested in a very rapid manner. In one of my patients, the effect was more prompt than by nitre fumigation or chloroform. In three cases of cardiac dyspnœa, I have also remarked the favourable phenomena. I have prescribed the same remedy in three cases of chronic bronchitis accompanied by dyspnœa, and the effect, though less prompt, was still marked. About eight days ago, I prescribed the inhalation of it in a case of œdematous laryngitis in a man, aged forty; for two days I hesitated about performing tracheotomy on account of the asphyxia and aphonia, but the patient was cured by repeated inhalations—ten to twelve a day.

OBSERVATIONS.—*Chemical Composition.*—Iodide of ethyl, discovered in 1825 by Gay-Lussac, is a mixture of two parts in volume of alcohol, with one of iodhydic acid. This ether, which has no acid reaction, has an odour of chloroform, a density of 1·92 to 2·2: it is volatile, and boils at 64 C., without being inflammable. Its formula, in equivalents, is $C_2 H_5 L$ (Berthelot). Atomic formula, $C_2 H^5 L$ (Wurtz).

History.—During 25 years it was forgotten, until Huette experimented with it on himself and on one of his friends, in the hope of replacing iodine, which Laennec, Berton, Pravez, Scudamore, Murray, administered under the form of inhalation, in pulmonary phthisis. The thesis of Huette appeared in 1850. The iodide of ethyl appears to have been forgotten, and I was, until lately, ignorant of the existence of this work; during the six months I was engaged on the application of iodic ether, I thought my ideas new. Huette did not, however, speak of its use in asthma.

Physiological Effects.—I have observed the following effects in healthy subjects, and sufferers from dyspnœa, after the respiration of six to ten drops of the iodide of ethyl, six or eight times a day. In health, after some seconds, respiration becomes freer, lasting for some hours; there are no anæsthetic or soporific effects; the heart's action and circulation are unaltered; absorption takes place almost immediately, for at the end of ten minutes the iodine may be found in the urine. An attack of coughing frequently comes on after inhalation.

Mode of Action.—Iodide of ethyl, and iodide of potassium have an indisputable action over the bronchial secretion, increasing it, and by the consequent greater fluidity allowing freer access of air to the pulmonary alveoli, thus the tympanic sonority of emphysema disappears. The sibilant *râles* of asthmatic catarrh are replaced by mucous *râles* as the first effect of iodine. In the second place the iodine acts on the respiratory centres through the circulation, which is rendered more active; the respiratory centre coming in contact with a larger quantity of blood is more excited, and thus respiration becomes easier. In the third place, ether combined with the iodine, facilitates in its turn respiration.

Conclusions.—1. Iodide of potassium constitutes the most certain means of curing asthma, no matter from what cause. 2. Iodide of ethyl cures attacks of asthmatic dyspnœa in a very rapid manner, and seems equally efficacious in cardiac and even laryngeal dyspnœa.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

At the meeting held February 18th Mr. Wm. Adams, F.R.C.S., read a communication to the Society on

THE TREATMENT OF BROKEN NOSE BY FORCIBLE STRAIGHTENING AND THE SUBSEQUENT USE OF RETENTIVE APPARATUS.

The Author exhibited some improved instruments for the treatment of broken nose, a subject which he had first brought before the Society in March, 1875. Mr. Adams divided the cases of broken nose into two classes — 1st, those in which the cartilaginous septum was depressed and bent laterally, so as to plug one nostril, obstruct the breathing, alter the voice, and produce ozæna by the decomposition of retained mucous secretion; and, 2nd, those in which the nasal bones were fractured in addition to the lateral bending and partial displacement of the cartilaginous septum. The operation which Mr. Adams had proposed was to straighten the bent cartilaginous septum by large flat-bladed forceps, and, where possible, to raise the lower margins of the fractured nasal bones, afterwards retaining the septum in a straight line with the vomer and perpendicular plate of the ethmoid bone by an ivory clamp, and also retaining the nose in an improved position by a nose-truss, worn externally. The large flat-bladed forceps originally used by Mr. Adams in 1861, when he first successfully performed this operation, had not been improved upon, but the retentive apparatus for the septum, and the nose-truss, applied externally, had been materially modified and improved, and various modifications were exhibited to the Society. The steel screw-compressor and the large ivory plugs were now replaced by the ivory clamp, with rack and pinion movement, first made by Mr. Ernst; and the retentive nose-truss, consisting of a broad metal forehead-band with two double action rack-and-pinion movement levers, with adjusting plates, had been greatly improved by Mr. Hawkesley. The necessity of retentive apparatus in cases of broken nose had been questioned by some surgeons from the absence of the causes of displacement by muscular action met with in the extremities and other parts of the body; but if it could be dispensed with in some cases of recent injury, Mr. Adams considered that it never could be dispensed with in cases of some months, and frequently of several years after the injury, and these were the cases which had generally fallen under Mr. Adams's observation. He especially drew attention to three cases now under his care, all occurring in young ladies between 13 and 16 years of age, who had met with accidents eight or ten years previously by falling downstairs, or similar injuries. Increasing deformity of the nose was observed at this period of development, and, upon examination, one nostril was found to be completely plugged by lateral bending of the cartilaginous septum. The breathing and the voice were both interfered with, and ozæna generally existed. In these cases the nose was completely and permanently straightened by the plan of forcibly straightening the septum, and afterwards continuing the use of the retentive apparatus, the ivory clamp being used continuously for three or four days and nights, and afterwards at night only, whilst the nose-truss was worn during the day for several months.

SURGICAL SOCIETY OF IRELAND.

The Fifth Meeting of the Session was held on Friday, February 1, 1878, Dr. Robert M'Donnell, President, in the Chair.

(Continued from our last.)

Dr. Henry Kennedy read a paper on

OBSERVATIONS ON SOME OF THE WAYS FEVER MAY COMMENCE; WITH A FEW CURSORY REMARKS ON ITS TREATMENT AT THE PRESENT DAY,

which will be found on page 165.

Dr. F. T. Porter asked Dr. Kennedy's opinion as to the use of stimulants in fever, as it was very hard, especially for young practitioners, to follow out any line of treatment where so many authorities differed on the point. With reference to his own experience, he had always remarked that where the first sound of the heart was in any way weak, stimulants were very well borne. With regard to the use of milk, it was scarcely wrong to give the five quarts mentioned in Dr. Kennedy's paper, when they remembered that the milk of the present day was too well watered. Perhaps it would have been well if Dr. Kennedy had ascertained the specific gravity of the milk in question. Dr. Kennedy seemed to regard it as the custom in this country, to leave the treatment of typhoid fever to Nature. He (Mr. Porter) did not think that was the case, and if they were proud of anything in the Dublin School, it was the successful efforts of the late Dr. Graves and the late Dr. Stokes in regard of fever.

Dr. Bigger said that he should be sorry that some of the opinions put forward by Dr. Kennedy should be taken as the opinions of the Society. Looking back to the days when he (Dr. Bigger) was resident in the House of Industry, and the Whitworth and Hardwicke Hospitals, he might state that there were three or four physicians attached to the institution, who each had a different practice. One was a man whose treatment of fever was unexampled in its success, compared with anything he (Dr. Bigger) had ever seen. He referred to Dr. John Crampton. And when he recalled the practice he pursued, and which he was obliged to carry out for him every day, he could not say he ever felt so delighted as he was with the results of Dr. Crampton's treatment. And he (Dr. Bigger) had the advantage of seeing the different ways and the results of the treatment of other men whose practice he had also daily to carry out. At that time, bleeding was considerably practised. He did not think that fever had altered in its nature, but he thought their practice had. Crampton used to bleed in fevers of all kinds, and strange to say he succeeded. He had known him to say, "If that man raves to night, give him plenty of wine." There seemed to be a kind of instinct about his practice, and he never could convey what its meaning was. His (Dr. Crampton's) idea of fever was very much what Dr. Kennedy had described in his paper as the fashionable practice, to let fever a great deal alone; and he (Dr. Bigger) believed he was greatly borne out in the fact that fever must run its own course almost in every instance, and he (Dr. Bigger) did not think he had ever seen fever checked by anything, but by an emetic. He believed that in the commencement of a fever, if a strong emetic was given, it would cut it short. That was almost the only thing he had ever seen have that effect, except immersion in cold water; he did not mean the practical adoption of that expedient. He remembered on one occasion, a boatful of troops, of which seven were in high brain fever, being capsized on its way to the shore from the ship, and the result of that accidental immersion, was that six of the men lost the fever. There was an incident told in connection with the rebellion in Ireland in 1798, and it was that one of the leaders of that rebellion, was being pursued by the troops, and he got into a house, and as there was a probability of his being taken prisoner if he remained there, he escaped into the garden of that house, and plunged into a pond there, although he was in a high state of fever, and supported himself, above the water by fastening his teeth in something. He was searched for, and could not be found, and when the troops went away, and he was got out of the pond, the fever left him. The other example of the kind might be mentioned, and a curious one too, that occurred in the Hardwicke Hospital. A man in fever, raving and very wild, was placed in charge of a nurse in one of the top wards, out of which he managed to steal in the middle of the night, got out of a window, and fell a height of 40 feet, breaking one of his arms. It was a frosty night, and he remained out some time. He then walked back to the door of the hospital, which was opened; he was readmitted. The next day that man was rid of his fever. There might not be much in those cases, but still he thought they were worth mentioning.

Mr. W. J. Wheeler asked, did Dr. Kennedy think there was any pyæmic tendency in the patients, in whose cases the joints swelled—in the scarlatina and typhus fever patients—because he (Mr. Wheeler) had seen some cases of fever, in which pyæmia had undoubtedly been present, and the joints had swollen?

The President said there were two or three points in Dr. Kennedy's paper, which struck him as being exceedingly valuable in a practicable point of view. He (the President) must say that in the little experience he had of these matters he quite agreed with Dr. Kennedy in thinking that a great deal of harm had been done by the idea of cramming fevers. He thought the anxiety of the mother to keep life in her child, and of the wife to keep life in her

husband by feeding him, did a great deal of harm in those maladies. In some of those cases, it was really almost like a person imagining he could keep in a fire, very nearly out, by throwing slack upon it. There was nothing that required—especially was that the case in typhoid fever—more judgment on the part of the physician, than the directions given to those in attendance on patients in such cases, nurses and so on, as the management of the nutriment, and the management of the stimulants. It certainly was the view more generally taken now than it used to be, that it was the tendency of those fevers which were regarded as morbid poisons received into the system, to run a certain distinct definite course; and so strongly were they imbued with that opinion, that in a case where the fever was cut short, he would be inclined to doubt whether the patient was in true fever to start with. Their idea was, that where a morbid poison had been received into the system, that scarlatina, small-pox, or any of those fevers which ran a definite course of disease, should be placed in categories by themselves; their idea from one point of view was that they were diseases, and in another point of view, that they were efforts of Nature to restore health. Nature struggled to get rid of these morbid matters, and to restore strength, and from that point of view, the wise and judicious physician was much in the same position as the wise and judicious accoucheur, who took his stand by the bedside, and waited on Nature. There was no nobler or finer vocation than that of the skilled accoucheur, who regarded himself as the assistant of Nature, whose office was to aid her in the accomplishment of a certain definite object. So in the present day, the same view had been extended to these various forms of fever, which were caused by morbid materials being received into the system, and which morbid materials passed out. He did not say that that theory of morbid poisons being turned out of the system by the natural efforts of the constitution, was at all at variance with the treatment suggested by Dr. Kennedy, who thought it was desirable to look for, and treat, the ulceration of the bowels. Dr. Kennedy thought it was desirable to look out for all the various accidents which were likely to happen in the course of these diseases, exactly in the same way that the skilled accoucheur was aware of certain dangers, and with great courage and determination combated those certain dangerous symptoms as they arose. He did not see anything in what Dr. Kennedy had stated that was at variance with the view that the wise thing to do was to recognise the fact that these morbid poisons had to run a definite course, and that the physician should stand by, and treat certain dangerous symptoms as they arose.

Dr. KENNEDY in reply, said he need not say that the object of the paper was not to enter into any specialities of treatment at all, nor was it easy to say that wine should be accepted as a general agent at all. It would not be possible to enter into such a subject there. A person must have experience of the matter, and of the state of the circulation and habits of the patient, and as regarded these matters the rules laid down by the lamented Dr. Stokes, were most valuable and important. He (Dr. Kennedy) did not know any class of patients in which the good effects of wine were better seen than in children. It was really marvellous. He had seen the most serious cases in Cork Street Hospital until they got a little wine, and then the patients got better. It was not right to have the use of milk, whether watered or not, over-done in these cases. It curdled in the stomach, and was thrown up; or else it remained there, and kept the fever up for days. In the case he had mentioned, where five quarts were given, the good effects of the reduction of the quantity to three pints, were immediately seen. The patient at once began to get better and lighter. Many individuals would not bear milk at all, and when such persons were made bilious by a small quantity of milk, it might be certain that they could not bear it in fever. He, therefore, thought it was better to inquire whether the patient would bear milk especially in typhoid fever. As regarded treatment, the Irish School had not those great principles that he had alluded to. On the other side of the channel, in London, or America, anyone who looked into the publications of the day, must find that what prevailed in those places, was a kind of "do nothing" treatment, with the positive knowledge before them, that they had certain kinds of inflammation to contend with, and that these were going on under the very eyes of the practitioner. He said, and believed, that they were bound to stop those inflammations as far as they possibly could. Stupes and poultices would not stop inflammation, it required more active treatment. In reference to what Dr. Bigger had said, he (Dr. Kennedy) was aware of cases where shock to the system, such as would be caused by the patient suddenly falling into water, had cut fevers short, and he believed that such shocks were quite capable of having that effect. In London, the cold bath (warm in the first instance, and then cooled down), had been tried, and the results of that treatment had been published, and anyone who read the reports of those cases, must say that the greatest possible caution was required in the use of those remedies. Several cases were given, where it happened that after the patients were taken out of the bath, they shivered, and those patients went on to their deaths. That was a tampering with the system that would not stand. Dr. Wheeler had spoken of the swelling in scarlatina, which formed such a terrible feature in that disease, but that was altogether different to what he (Dr. Kennedy) had spoken of, which were cases of nothing but rheumatism, where every joint was attacked, and that rapidly disappeared. If it had been pyæmia, it would not of run that course.

The Society then adjourned.

DUBLIN OBSTETRICAL SOCIETY.

THE Third Meeting of the Session took place on Saturday, January 13th, 1878, the President, Dr. DARBY, in the chair.

PUBLICATION OF THE PROCEEDINGS.

Before the ordinary business of the Society commenced considerable discussion took place as to the desirableness of discontinuing the publication of the Society's Transactions in a separate volume, owing to the present financial condition of the Society. Dr. Lombe Atthill moved a resolution to the effect that the publication of the Transactions of the Society in a separate volume be for the present discontinued. He said that his motion in no way interfered with the ordinary publication of the Society's Proceedings *in extenso* in the journal which had hitherto been their organ. Dr. M'Swiney seconded the motion. Dr. Fitzpatrick considered that it would be most desirable that the Society's Transactions should appear in a separate volume, not yearly, but whenever the Council considered it necessary, and the papers read at the meetings should be submitted to the Council, who should decide whether they were or were not worty of publication. He moved an amendment that the publication of the Proceedings of the Society be continued at distant dates, subject to the discretion of the Council. Ultimately the amendment was negatived, and the original motion carried.

THE LATE DR. WM. STOKES.

Dr. M'CLINTOCK.—I think we should not be acting justly to ourselves—I think we should be wanting in self-respect, if we allowed this opportunity to pass—the first meeting of the Society that has taken place since so great and illustrious a member of our body of the physicians of Dublin has been removed from amongst us—if we did not mark our sense of the loss we have sustained; and I am desirous of submitting a resolution, that I am sorry to say has not been drawn up with as much care as I think the matter of it deserves, to this meeting for its adoption—with reference to the decease of Dr. Stokes. As so much time has been occupied by the discussion just concluded I will not detain the Society by any further observations, but will move the following resolution:—"That this Society, in common with the other medical and scientific bodies of this city, desires to give public expression to its deep and heartfelt regret at the death of Dr. Wm. Stokes, Regius Professor of Physic in the Dublin University, and desires to record its testimony to his prominent abilities as a physician, and to the distinguished services he had rendered to the Medical School of Dublin, and to his many great qualities of head and heart; and also that the sincere condolence of the members of the Society be respectfully communicated to his family."

Dr. ROBERT M'DONNELL, F.R.S. (President of the College of Surgeons) most heartily and sincerely seconded the resolution.

The resolution was then carried by acclamation.

Dr. S. R. MASON exhibited

A MULTILOCULAR OVARIAN TUMOUR,

which had been removed that morning by Dr. Kidd in the

Coombe Hospital. The patient was an unmarried woman, æt. 26, who was very much reduced by several severe attacks of peritonitis, which usually occurred at the menstrual period. The abdomen was laid open by an incision about three inches long, which was subsequently extended upwards to the umbilicus, in order to find a portion of the tumour which was not adherent to the abdominal walls. When the tumour was fully exposed a large fleshy mass was found lying on its surface extending from the right side to the centre of the tumour, where it was attached. The tumour having been tapped this fleshy mass was secured by a temporary clamp, and was detached by dividing the cyst wall around its attachment, when it was found that it formed the pedicle, which had become displaced by the tumour being rotated on its own axis from the right to the left side. The cyst itself had to be separated from the small intestines and from the walls of the true pelvis, to both of which it was very adherent. The pedicle was afterwards tied with a hemp ligature, which was cut short and returned into the abdomen. The wound was closed in the usual way by hemp sutures, the lower one being loosely tied in order to allow fluid to drain out. In examining the tumour after its removal it was found that a small piece of bone was situated on its left side, which could be easily felt through the abdominal walls before the operation.

Dr. M'Clintock reported to the Society the particulars of a

CASE OF TRANSFUSION

which occurred in his practice. He said that early in the month of August last he was called to a distance of several miles from Dublin to see a lady who had been taken with the pains of labour. It was her fourth labour, and the pains commenced about nine o'clock in the morning. He reached the bedside at two o'clock, at which time her state was most alarming. It seemed that an hour after she became ill it was ascertained that a presentation was preternatural, and it was thought it might be an arm—a cross birth. At eleven o'clock very profuse hæmorrhage set in, and when he saw her at two she was nearly insensible, and almost pulseless. She was reported to have had two slight convulsive seizures, and when he examined the bed he found that she was literally surrounded by an ocean of blood, the whole of the bed and bed-linen being saturated. On turning the patient over on her side to institute an internal examination, he was fortunate enough to find a leg in the vagina, and on taking hold of it and making traction, with very little effort the child was delivered, but it was quite dead. The placenta came away after slight pressure, and there was no more hæmorrhage. The patient rallied a little, but on gathering from the evasive replies given her that the child was dead, the effect of her disappointment was so great that it seemed at once, as it were, to utterly paralyse and prostrate her. She never spoke after that, for several hours after transfusion was performed. Dry linen was put upon the patient's person, the bed was re-arranged, stimulants were used, and so forth, and every possible means at hand was used to try and bring about reaction. There was no hæmorrhage from the time of delivery, and the uterus contracted tolerably well. The position of the body was altered, the lower limbs being elevated, and the head kept very low, and in addition to that he repeatedly made hypodermic injections of sulphuric ether, which used to impart a momentary increase of her strength and vitality. After waiting for some hours with scarcely any pulse to be felt at the wrist and no decided turn for the better taking place (things went on in that way for six hours), and all the remedies to bring about re-action having been tried without any improvement whatever in the condition of the patient, who never spoke, whose surface was cold, and whose pulse was just barely at times perceptible at the wrist, it was decided that the only chance there would be of saving the patient's life would be by the performance of transfusion. He did not recollect in his experience seeing a case in which reaction was so long deferred, and the patient recovered eventually. A messenger was at once dispatched for Dr. Robert M'Donnell, who promptly came, but before he reached the house nine hours had elapsed since the patient was delivered. The blood was obtained and defibrinated, and they at once set about the operation. The blood was injected to the amount of about ten ounces into the arm without any difficulty, except the difficulty of finding the vein owing to the extremely anæmic condition of the patient. At that time the patient was quite insensible, and offered no violence. After a few ounces of the blood had been ejected he discovered a slight improvement in the condition of the pulse. Nothing of any particular importance whatever occurred in the operation. After the blood was injected the arm was bound up, and the pulse by that time was somewhat further improved. In the course of a few hours subsequently a decided indication of reaction began to show itself, and at the end of about twelve hours complete reaction was established. From that time forward no case could go on better or more satisfactorily towards convalescence, and she made a perfect recovery in every respect from the time of the performance of the operation of transfusion by Dr. Robert M'Donnell. He might mention that Dr. Malachy Burke, and Dr. Stanistreet, of Malahide, were present, and assisted during the operation.

Dr. Macan (for Dr. Purefoy) also read a paper on Transfusion, in the course of which the author described a case in which Dr. Robert M'Donnell successfully performed the operation at the Rotunda Hospital.

Dr. Robert M'Donnell (President of the College of Surgeons) thanked Dr. M'Clintock and Dr. Purefoy for having brought forward these cases. He (the speaker) observed that it was impossible to say with anything approaching absolute certainty whether life was really saved by this method of treatment. But in that respect transfusion did not differ from any other method of treatment. He would only say that where death appeared to be imminent, and where the most experienced practitioners considered life to be in the extremest degree of jeopardy, by that treatment the danger seemed to be averted. But whether life was actually saved or not one thing was certain, that in no single instance had the very grave consequences which some persons apprehended as likely to happen where defibrinated blood was used—in no single instance had those ill consequences taken place. In no one of the cases that recovered did ecchymosis or bloody urine or hæmorrhages of any kind take place; convalescence was speedy and complete. Dr. M'Donnell, in conclusion, said he looked forward to making a further communication to the Society on the subject of transfusion, when he would bring together the cases in which he had successfully adopted this procedure.

The President said he had seen Roussel's transfusion apparatus in use at the last meeting of the British Medical Association at Manchester, and it failed in the stabbing process which it instituted for opening a vein. Six times it failed, the vein rolling away from the lancet on each occasion, and the incision in the skin being immediately over the vein. After three or four more attemps the vein was at last opened. When the vein was ready to inject the blood the instrument again failed, because the blood coagulated in the small valves so that not one drop of blood was injected into the patient.

Dr. B. W. Richardson asked the President if he had observed the length of time it took to make the instrument work.

The President said he was watching the experiment he had referred to for about half an hour.

Dr. Henry Kennedy alluded to the number of cases in which transfusion was performed in the cholera epidemic, and mentioned the circumstance of a dog being bled apparently to death from the jugular vein, and then tepid water being injected, the result of which was that the dog got up and staggered about, though a moment before he seemed dead. He therefore thought if they were driven to it that they would be quite justified in injecting tepid water under the circumstances.

On the motion of Dr. Macan, seconded by Dr. Cranny, the debate was adjourned until the next meeting of the Society.

The Sussex County Hospital, and the Isle of Wight Infirmary, have each received £1,000 by the will of the late Lady Harcourt. The Cumberland Infirmary has received £2,000 and £500 under the will of the Rev. C. J. Denton and R. Carruthers, Esq., respectively.

A valuable silver salver and a service of plate, to the value of £260 was presented last week to Dr. John Osborne, of Bitterne, together with an illuminated address on vellum, in testimony of the esteem in which his services are held by his patients and friends.

THE "MEDICAL PRESS" SPECIAL REPORT
ON
THE NATURE OF RABIES,
ND THOSE DISEASES RESEMBLING IT,
IN WHICH
HYDROPHOBIA IS A PROMINENT SYMPTOM.

CHAPTER X AND LAST—HISTORICAL AND BIBLIOGRAPHICAL.
(Concluded.)

IN the Sixth Century we have evidence of its existence in the writings of Themnestus, who in his "Geoponica" has devoted some attention to it. Paulus Ægineta, who, according to Abulpharagius (1) lived in the Seventh Century has compiled a very good account, from the writings of previous authors. He distinguishes between the disease due to the bite of a dog, and the simple curable nervous disease arising from other causes. He observes that the result of inoculation was always fatal. (2)

"Cæterum eorum qui, in hanc affectionem inciderunt nullum sanatum esse."

Our chain of historic evidence for this period is almost completed by the writings of Jahiah-Ebn Serapion, a native of Syria, who believed that the disease produced by the bite of a mad dog was incurable, and who proposed that the patient should be made to swallow water by enclosing it in a globule of concrete honey. (3)

It is mentioned by Rhazes (died A.D. 932), (4) an Arabian physician, who says that a certain man barked by night like a dog, and died; and there was one, who when he beheld water, was seized with trembling, horripilatio, and rigor—but when the water was removed from him, these symptoms ceased.

We have some old Anglo-Saxon manuscripts, supposed to belong to the Tenth Century, which contain remedies and incantations wherewith to cure or exorcise the disease. In one of these, a Saxon Herbarium, are a number of curious recipes.

In the year 825 A.D., several people are said to have been cured by resorting to the shrine of St Hubert, in the Ardennes, a practice in vogue even in the present age. (5)

From the Tenth to the Nineteenth Century.

Avicenna (6) (B. 980. D. 1036), the Arabian physician, marks a further step, both in the history of the disease and in the advance of our knowledge thereupon: his treatise being marked by accuracy in observation and completeness. The ashy tint of skin, oftentimes designated by the term rabic (7) roseola, noticed by many observers, as Codrondius, was first observed by Avicenna in the dog.

In the laws of Howell the Good, of Wales, which were revised about the year 1026, we are informed of the earliest mention of the disease in our own country. (8)

In the twelfth century Demetrius Pepagomenos, a Greek writer, who lived at Constantinople, is supposed to have referred to this disease in his work entitled the "Kynosophion," whilst in the thirteenth century it is alluded to by Albertus Magnus, Bishop of Ratisbon, and by Laurentius Rusius, a century later.

Between the years 1500 and 1600, the literature began to expand, and we have the names of Montisianus, Paré, Mercuriali, Frascastor, and Baccius, as contributors

In 1613 Spackmann published a work entitled "A declaration of such grievous accidents that commonly follow the bites of mad dogges," and this we may consider the first English work on the subject; during the next century the literature expanded into almost alarming proportions, especially on the Continent.

English writers shared in the general desire to clear up the nature of the malady, and we have many interesting and valuable works as the result of their exertions.

We may notably mention the names of Nugent (1753), James (1760), Bruce (1765), Layard (1762), Heysham (1777), Fothergill (1778), Vaughan (1779), Berkenhout (1788), McIlwaine (1787), Foot (1788), Hamilton (1798), and Bush (1797). At the beginning of the nineteenth century a stimulus was given to the subject, by the prevalence of the disease, and we have consequently a number of treatises, notably those of Lipscombe (1807), Moseley (1809), Powel (1809), Gillman (1812), Parry (1814), Marshall (1815), Reid (1817), Blain (1817), and Youatt (1836). After this period in England we find a wide gap until we come to the year 1871, when Fleming published "Animal Plagues, their History and Prevention," followed in the year 1872 by his work, now classic, "Rabies and Hydrophobia." No doubt, in England the rapid extension of medical periodicals tended very much to diminish the number of special treatises, whilst the various handbooks on general medicine and surgery also explain the paucity of monographs, as they all contain special articles on the nature of the disease. During the present century, Continental writers have produced works with inexhaustible rapidity. In our "Bibliographical Record" will be found the names of the principal works published, and we can only briefly mention one or two of the most interesting.

About the beginning of this century, Bosquillon (1802), suggested that the virus of rabies was only a chimera, and that fear alone was the great factor in its production; in this view he was supported by Girard, and we believe there are some at the present day who are still of this opinion. French veterinarians have paid particular attention to the disease, and we may mention, in particular, the name of M. Bouley, as one of the most accurate and reliable authorities of the present age; he has enriched the literature of rabies by many valuable contributions. The interest excited by this malady is well illustrated by the extent of the literature, and though it is a matter of regret that the production of so many works has produced so little proportionate benefit, still they are evidences of the desire and ambition of our profession to place rabies on a more satisfactory footing. Future writers have an inexhaustible mine to work at amongst the old writers, and in order to facilitate reference we have arranged a biblographical record, which we have endeavoured to render as complete as possible.

Geographical Distribution of Rabies.

We have evidence that the disease has prevailed amongst animals, as the dog, cat, wolf, hyena, fox, &c., over a wide extent of the world, and it has been asserted that no land or climate is free from rabies. European countries, as Germany, France, Italy, Austria, Holland, and England appear to have suffered from it most extensively. It was at one time believed it was confined to climates of moderate temperature, and that warm countries, as the East, Egypt, Turkey, and South America, were free from its ravages. More extended observations have proved the fallacy of this belief. Extreme cold regions were also considered protected, but the erroneous conclusions of earlier observers have been upset by other more comptent and later travellers. The disease has been observed in various animals under the most opposite temperatures in the following countries and localities:—

Abyssinia (North) (1), Africa (2), America (North and South) (3), Arabia (4), Asia (5), Affghanistan (6), Algeria (7), Arctic Regions (8 & 9), Brazil (10), Ceylon (11), China (12), Cochin China (13), Denmark (14), San Domingo (15), Damascus (16), Egypt (17), Gibraltar (18), Guadaloupe (19), Holy Land (20), Havanna (21), Hispaniola (22), Hayti (23), India (24), Jamaica (25), Indies (West) (26), Mexico (27), Mauritius (28), Malta (29), Norway (30), Peru (31), Russia (32), Roumania (33), Syria (34), Sweden (35), Turkey (36), Constantinople (37), Smyrna (38).

Probably it has been introduced into many countries by communication with Europeans. A few countries have yet escaped, as Australia, New Zealand, the Azores, and St. Helena: at least, we have no conclusive evidence up to the present that rabies has been noted or recorded there.

The human subject is liable to the disease, and exposed to the danger of infection in every country where it exists in animals. We may state, on our evidence, that colder climates do not seem to suffer so much from its ravages.

A very significant return has been obtained from the Registrar-General for Scotland, the slight mortality in that country contrasting with the high death-rate in England, and from this we may draw an inference that the northern parts of our island are not so exposed to this plague. The nominal death-rate of England might probably be lowered if the Registrar-General adopted the step taken by his *confrère* in Scotland, viz., by expunging from the assigned nomenclature reputed cases of hydrophobia, and classifying them under their more correct appelation.

We have mentioned the influence of seasons and meteorological conditions to which we cannot attach any perturbating influence in the production of the malady.

In concluding our report we must draw the attention of the profession to one important subject. Rabies illustrates the close connection existing between human and veterinary medicine. Our knowledge of rabies would have been limited, but for the researches of such veterinarians as Blaine, Youatt, Bouley, Pillwan, Bollinger, and Fleming,—and society and humanity in general, owe a debt of gratitude to the sister profession for the labours which have furnished our profession with the groundwork upon which all our knowledge is based.

Human pathology cannot be divorced from its twin sister, comparative pathology, and we thoroughly agree with the aspiration of Fleming, that it is to be sincerely hoped both branches of medical science may ultimately be looked upon as one, and that the benefits to humanity, to be derived from their union, may be fully realised.

Veterinary medicine has of late years occupied a larger share, both of the attention of the public and of the Government. Much may yet be done to advance our knowledge of the actual existence and extent of rabies in Great Britain, amongst all classes of animals. The veterinary schools might usefully assist by the publication of annual statistics on the prevalence of the disease, whilst Government might valuably aid by sanctioning the annual compilation of returns from the various districts under police supervision. We have said that the problem alone can be solved by a large accumulation of facts, and we have contributed our quota for this purpose. We have endeavoured to lay before the profession our existing knowledge on rabies, so that our Report might form a *point d'appui* for future workers, and we feel gratified that we have been the cause of stimulating further scientific inquiry into the nature of this affection. Science has alone for her object, Truth—and we feel, in the interests of science, a pleasure in leaving further investigation in the hands of such competent experimenters as Drs. Burdon Sanderson and Lauder Brunton, to the publication of whose researches we look forward with interest and hope.

CASE CLIV.—G. H., female, æt. 14½, mill hand, previously always healthy. On March 3rd, 1875, she was giving a cat some milk, when a pup nine weeks old, of Scotch terrier breed, snapped at her and bit the first finger of her right hand on the inner side of the nail. It bled a drop or two, and appeared all right in two or three days. The pup had not been well for a day or two, had refused food and drink, but there was no vomiting, and no saliva noticed about the mouth. During the afternoon of the same day, it snapped at and scratched slightly, the hand of a younger sister. The father thought he would destroy it; whilst taking hold of it, it seized his thumb, and bit him rather severely, causing a wound, which bled freely. It was then drowned by the mother.

Result and Time of Attack.—Between six and seven weeks after. Fatal, third day.

Treatment.—Chloroform, hypodermic injections of morphia and injections by the rectum of chloral hydrate, which relieved the severity of the spasms.

Remarks.—The father and sister, who were bitten by the same animal, continued in good health. I may mention that in 1849 some cases occurred at Queensbury. From memory I send a *resumé* of the facts. A party of young men were at the Granby Inn, when a strange dog came in and got under the long settle; in the attempt to dislodge it several were bitten. Six weeks afterwards one died. At the inquest another, who had also been bitten, showed the mark on his hand; in a fortnight he was taken ill and died.

Reference.—Notes kindly furnished by J. H. Bell, M.D., Bradford, Yorkshire.

CASE CLV.— ——, female, æt. 24, bitten by a dog suspected rabid. The wound was burnt with caustic soda three days afterwards.

Result and Time of Attack.—Eighty days after. Recovery.

Treatment.—After having tried the injection of morphia and inhalations of chloroform without any benefit, it was decided to try full doses of curara, seeing the good results which had been obtained in tetanus. A subcutaneous injection of two centigrammes of curara (about one-third of a grain) in water was administered. This was three hours after the sudden onset of the disease. A quarter of an hour later, there having been no visible effect, the dose was repeated, after which the condition began slightly to improve—that is, there were longer intervals between the spasms, and the muscular movements became less, and finally ceased. This result induced a continued trial of the same treatment. The injections were continued, a somewhat larger dose (three centigrammes) being used. They were timed in such a way that an interval sufficiently long between the doses was allowed for the physiological action of the drug, and for any manifestation of the curara-intoxication to be obtained. Thus, at twelve o'clock the third injection was given, and the intervals of spasm became longer. In an hour another injection was ordered, and the intervals again became longer. At the same time the feeling of anxiety and oppression was less intense. A fifth injection was given at 2 a.m., and a sixth at 2.30. The intervals between the spasms now extended to ten minutes, and the pain in the chest and throat was almost gone. Indeed, there was a peculiar condition of hilarity and talkativeness, instead of the previous anxiety. Then the first appearances of loss of voluntary power just began to show themselves. After one more injection (the seventh) at 3.20 the spasms ceased entirely, and symptoms of a general paralysis of all voluntary movements became quickly apparent. The eyelids could only be moved with difficulty; there was difficulty also in speaking. Breathing continued normal; only twice was there any arrest of respiration, and this was overcome easily by making one or two rhythmical movements with the abdominal parieties; the breathing then continued regular. After these toxic effects had lasted with this intensity about two hours, movements again became freer. Some hours after the last injection of curara, it was seen that the dread of water no longer existed, as the girl could drink freely without any difficulty whatever. The sensitiveness to light also disappeared, and indeed all the symptoms of hydrophobia subsided. Thus within four hours and thirty-five minutes seven injections had been administered, representing altogether nineteen centigrammes of curara. During the course of the next few days, a mixture of symptoms, partly arising from the curara, and partly from the effects of the recent disease, developed.

The latter consisted of slight muscular movements and involuntary spasmodic respiratory troubles, which for the most part were produced by the irritation of drinking, or fright, though they occurred spontaneously every now and then. On the evening of the next day but one, some of these symptoms assumed a serious aspect, and another injection of curara was at once ordered, after the administration of which they disappeared. These symptoms, though of much less intensity, continued to recur until the eighth day, after which they finally disappeared. The girl was discharged cured on December 3 of the same year, and went into service a few weeks later. She is now in perfect health.

Dr. Offenberg's Remarks.—The favourable action of curara in human hydrophobia may be explained as follows:—The chief symptom certainly is the frequent spasms. These spasms, which become more violent after each attack, are the cause of the constantly increasing danger of the disease, and they are finally the cause of death, which results either from exhaustion or from acute asphyxia. Curara, unlike other narcotics, does not act directly on the nerve-centres, but seems to act rather on the peripheral nerves. Its chief action seems to consist in paralysing the motor nerves, and especially (and soonest) those of the voluntary and striped muscles; then, after large doses, those of the involuntary muscles. An animal to which large doses of curara have been administered cannot move about voluntarily, neither can reflex movements be produced. If the motor nerves or even the spinal cord are irritated by a very strong electric current during the action of curara, muscular contractions cannot be produced; the muscles seem to be cut off entirely from the nervous system. The administration of curare in hydrophobia is not new. Niemeyer seems to have been the first to have tried it. He injected in his case five milligrammes, and then one centigramme, at intervals of three or four hours. "This treatment seemed to be of temporary service, and to produce greater relief than very large injections of morphia." Niemeyer strongly urged a further trial of this drug in larger doses in other cases of hydrophobia. No other successful results seem to have been obtained. Gualla has used curara in four cases of hydrophobia, and without success, but it is doubtful whether his doses were large enough. Theoretical arguments, no less than the above case, seem to indicate that the paralysing effect of curara is necessary to secure success. This case also proves that life may be sustained in spite of general muscular paralysis, the chief effort being, of course, to keep up respiration by artificial means. There is less danger of cardiac paralysis. It is a misfortune that a definite dose of curara cannot be indicated, the doses variously allowed by authors ranging from one milligramme to fifteen centigrammes. The difference depends, probably, on the quality of the drug. Another explanation, however, may be given. The action of curara depends chiefly on the excitability of the nervous system. The greater, then, the excitation and the excitability, and the greater the psychical exaltation, the more violent and intense will be the spasms, and the greater, therefore, must be the amount of the curara to hold these spasms in check. Thus, not only in different cases, but also at different periods in the course of the same case, entirely different doses of the same preparation will be indicated. A dose of curara, such as in a healthy individual with a normal nervous system would produce decided effects on the motor powers, would produce scarcely any effect whatever on one who is the subject of hydrophobia. The knowledge of this circumstance is of great importance, and we may commence at once with larger doses than we should probably otherwise employ; yet the difficulties of administering the drug are only partially overcome, especially as we have to administer it until we get paralysing effects. Obviously the safest way, then, to administer curara is to give small doses, and to repeat them at short intervals until the effects we desire are brought about; and as a subcutaneously injected dose is absorbed and commences to act in a few minutes, and further, as (according to Demme) the action of a dose of curara only lasts from four to five hours, so then we may most surely and safely obtain the effects of curara by oft-repeated small injections. Thus, if an injection be practised every half hour—a period of time which largely suffices in order to get the action, and the whole action, of an injected dose of curara—we shall be able within four or five hours to make eight to ten injections. In using curara in this manner, we not only secure its physiological action, but also guard ourselves against any sudden and too energetic manifestation of its toxic qualities. The action of small doses is proportionate both in intensity and duration, and so soon as any dangerous symptoms show themselves, we should withhold its further administration, and take precautions suitable to the occasion, as in the case just given. It is of importance to commence this treatment early on in the disease. If the spasms are still slight, very small doses will suffice; if they have become more intense, a corresponding dosage will be indicated. It must be remembered, however, that any possible toxic effect will also be proportionate to the dosage. Nor must it be forgotten that the administration of such a remedy itself produces spasms; the irritation of the injection-puncture may sometimes be so great that the patients will seriously dread it. The various precautions to take, then, and the dosage, will depend on the individual case, and must be left to the discretion of the surgeon in charge.

Reference.—Veterinary Journal. Dr. Offenberg, Prussia.

General Summary of Cases.

Under the generic term "hydrophobia," we found the cases we have collected from the various treatises and journals consulted. Our records are imperfect, for those who have reported cases have but too often omitted to note many essential points, and we have had for some cases to accept such evidence as the report of a non-medical paper. In the future, it is to be hoped, such errors will be avoided, and that reporters will give all possible information as to the animal which inflicted the bite, whether spaniel, terrier, &c.; whether rabid or not, and also note whether preservative measures of any kind have been adopted. We have mentioned other particulars which might advantageously be included in such reports, in our introductory chapter.

French writers afford us excellent examples of method in this respect.

The cases, however, afford ample evidence:—

1. That during the present century medical men have had but too many opportunities of studying the nature of this affection, of becoming acquainted with its symptoms, and of advancing our knowlege of its pathology.

2. That under the head of "hydrophobia," numerous cases are included, which have no analogy with the specific disease, produced by the bite of a rabid animal. The distinctive symptom "hydrophobia," so named, may occur in other affections, characterised by symptoms, equally distressing, intractable, and oftentimes fatal.

3. That nearly every form of treatment has been employed, suggested either by superstition, empiricism, or reason.

4. That there have been numerous reputed cases of recovery, some of which are undoubtedly genuine.

We have appended short *post-mortem* notes, which are also imperfect, but may prove useful by showing what has been done in the past.

Lipscomb asks why modern dissection has not improved our knowledge of the disease, and answers, how can it be expected? In the greater number of cases, the appearances after death have been governed by the various medicaments employed for the relief of the patient.

The examination in many cases has been conducted by observers who have not had sufficient experience to distinguish between the different causes by which similar effects might be produced. The dead body has been examined with a sort of bias towards considering the disease, as the cause of all the appearances by which that body is distinguished from others; sometimes without any knowledge of the medicines which had been exhibited, without any previous information respecting the habits of the patient, and without any consistent ideas of the influences and effects of the several circumstances in producing what are often improperly denominated morbid appearances. A judicious and experienced physician should have no difficulty for accounting for inflammatory streaks and spots on the stomach of the patient who, during the disease under consideration, swallowed large quantities of nitrate of silver or arsenic solution. It may sometimes be almost impossible for the most enlightened practitioner to determine in how great a degree the appearances after death may have been influenced by spasmodic contraction of the muscles partially or generally. While, therefore, we lament the want of a more correct history of *post-mortem* appearances, we must hope that our contemporaries and successors may furnish more reliable data.

RESUME OF CASES REPORTED UNDER THE NAME OF HYDROPHOBIA.

F. denotes Fatal; R. denotes Recovery.

NOTE.—Nos. 89 to 98, inclusive, are illustrative cases of so-called "Hydrophobia" quoted by Holland and Shinkwin.

THE death-rate last week in the four principal cities of the United Kingdom was at the rate of 28 per 1,000 of the population in London, 26 in Edinburgh, 26 in Glasgow, and 36 in Dublin. Of the large towns in the second category, Liverpool 32, Salford 33, Wolverhampton 38, Norwich 39, Manchester 39, and Plymouth 41, showed the highesf rate of mortality, whifst Portsmouth gave the most favourable returns, 16 per 1,000.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 27, 1878.

THE DENTAL PRACTITIONERS BILL.

THE following is the report of proceedings in the House of Commons in reference to the Bill to which we referred last week.

Sir J. Lubbock moved the second reading of this Bill, the object of which, he said, was to protect the public against quacks. The law very wisely provided that any person pretending to be a physician or surgeon unless properly qualified was rendered liable to a severe penalty. Chemists and druggists were not allowed to pursue their respective callings unless their qualifications had been tested by examination. It certainly seemed very anomalous that any person might call himself a dentist without the slightest qualification. Yet the profession of a dentist was by no means simple or easy. The system proposed in the present Bill had been tried in America and in Canada, where it had worked very successfully. It was proposed to respect vested interests; nor, indeed, was it proposed to prevent anyone from pulling out teeth and acting otherwise as a dentist, but only to forbid him from using a title which would imply that he had special qualifications. (Hear, hear.)

Dr. Cameron moved the adjournment of the debate, and after a short conversation,

The House divided, and the numbers were—

For the adjournment	27
Against it	49
Majority	—22

Sir J. M'Kenna moved the adjournment of the House.

Mr. Cross opposed the adjournment, which was supported by Dr. Cameron and Mr. O'Sullivan, who thought that the hon. baronet might congratulate himself on the passing of one of his Bills that evening. (Hear, hear.)

The House divided—

For the adjournment	11
Against it	61
Majority	—50

Mr. Dillwyn moved the adjournment of the debate.

Sir J. Lubbock said he should not further oppose, and the second reading was postponed until the 5th of March.

Respecting these proceedings, the *British Medical Journal* says, Mr. Lyon Playfair had been induced to withdraw his intended opposition by an unfounded statement made to him, to the effect that the Parliamentary Bills Committee of the British Medical Association did not make any objection to the Bill. Bound by the pledge which he had given, upon this statement being made to him, Mr. Playfair was unable to oppose the second reading. Mr. Cameron of Glasgow, with whom the Chairman of the Parliamentary Bills Committee had communicated during the day, kindly rendered efficient service, with other members who were opposed to the plan of this Bill, in succeeding in defeating its second reading. The most important lesson to be learnt from the foregoing debate is the support given to Sir John Lubbock by the Home Secretary, whose objection to the adjournment at once raised the number of supporters of the second reading from 49 to 61, and, correspondingly, reduced the phalanx of opponents from 27 to 11. There must, we presume, have been some reason (other than the merits of the measure) why the Government should use its influence to have so objectionable a measure read a second time, and the thanks of the profession are due to Dr. Cameron, and those who aided him to defeat the measure. The attitude of the Government ought, however, to convince the profession that their energetic action is at once required. They must act for themselves by petition, and by the exercise of influence with their representatives, for the Medical Council is as usual, entirely insensible to the emergency, and some of the colleges are involved in the support of the Bill, and cannot speak against it. Medical opinion is firmly united in a universal condemnation of this Bill, and in an emphatic protest against the proposition to make surgeon-dentists of all who can find money to buy a name-plate between this and January next, but there are important differences of opinion within the profession as to the amount of education which ought to be required from the dental surgeons of the future. Many surgeons, and most of the highest rank in the dental profession, maintain that a dentist should be a surgeon first and a dental specialist afterwards; that no one should be recognised as a dental practitioner except a duly qualified surgeon, and that if it pleased him to take a special license in dentistry that qualification should be additional to his surgical qualification. In support of this view it is argued: *Firstly*, that the skilful practice of dentistry involves a complete knowledge of the subjects correlative to surgery, and that a dentist cannot treat teeth diseases without an acquaintance with all branches of the education of the medical profession. *Secondly*, that no licensed speciality separate from surgery is recognised in the case of ophthalmology or gynæcology, and that it is not desirable to encourage the splitting up of medicine into a variety of specialities. *Thirdly*, that surgeons who now are alone recognised as legally qualified practitioners in all branches of their art (including dentistry) would suffer injustice if others, not educated or licensed as surgeons, were admitted to the legal practice of this part of surgery. *Lastly*, that great opportunity would be afforded for the practice of all branches of surgery by unqualified persons if they were once permitted to engage legally in any one of those branches. These are

the arguments put forth in favour of maintaining intact the present privileges of the profession, and, as such, they are entitled to our sympathy so long as they can be made to agree with the necessities of the public and the actual *status quo* in which we live. But it will be admitted, we think, that these arguments are disproved by a reference to the condition of dental practice throughout the three kingdoms. In the first place, it will not be denied that, whether or not the profession recognises dentistry as distinct from surgery, the public does so recognise it, and dentists who are not surgeons are as much a matter of fact as it is possible for any legislation to make them. The reason for this is obvious. It arises from the fact which those who argue in favour of the identity of surgery and dentistry would deny, from the fact that dentistry is not a limited speciality capable of being learned (at least to an extent sufficient for average practice) in a short time, and, therefore, within the reach of many who could not engage in the study of surgery. It is really futile to maintain that a man cannot be a thoroughly good dentist without having learned the anatomy, pathology, and surgery of the whole body, and this observation applies to the surgery of the teeth with much greater force than to ophthalmology or obstetrics, because the dependence of diseases of the teeth, jaws, and face, upon the state of the general system is much less close than in the case of these specialities. It might be said, indeed, with truth, that at least two-thirds of the study and money which is required by the surgeon for his complete qualification would be altogether thrown away the moment he narrowed his practice to dentistry, and it is, therefore, neither practical nor reasonable to compel a dentist to expend that labour and money on that which he has no need for before he can commence to learn that which he really wants. It would, surely, be anomalous that a dentist, whom competition might compel to accept very small fees, should be forced to have a higher qualification than his neighbour the surgeon, inasmuch as he should superadd a dental licence to the surgical licence which entitled him to all forms of medical practice. We therefore hold that a licence in dentistry, separate and distinct from the surgical qualification, should be provided by the surgical colleges in order that the requirements of the public may be met. We do not for a moment suggest that the right or capacity of the surgeon to practise dentistry should be open to doubt; on the contrary, we should look upon the surgical diploma as the higher degree in dentistry to be obtained by those who desired a more honourable qualification than that of L.D.S. We insist, however, that if any person is to be admitted even to a nominal association with the profession, he should pass through a thorough test as to his competency, and, therefore, so far from condemning the object of Sir John Lubbock's Bill *quoad* the legal separation of dentists from quacks, and the establishment of proper examinations, we entirely approve of these objects, and hope yet to see a measure for these purposes passed. Nevertheless, we repeat unreservedly our condemnation of the Bill as it stands.

An addition to the Fulham Small-pox Hospital, costing £5,250 has been decided upon by the Metropolitan Asylums Board.

THE NEW CHARTER OF THE IRISH COLLEGE OF PHYSICIANS.

Exactly this time last year the Fellows of the King and Queen's College of Physicians in Ireland received from Sir Michael Hicks-Beach a reply to their request for a new Charter, and that reply was in the form of a memorandum of a conversation between the President and Vice-President with the Chief Secretary. In this communication Sir Michael Hicks-Beach expressed himself as follows :—

He said that he did not like the notion of election by ballot for the Fellowship; but that if the Fellows were elected by examination or otherwise, and a Council was established, he saw no objection to the election from the body of Fellows to the Council by ballot.

With regard to the formation of a new order of members, the Chief Secretary considered that the enlargement of the number of Fellows, and the establishment of a Council, would render this unnecessary, inasmuch as he presumed that the higher order of Fellowship would entitle the holders thereof to all privileges attainable under a new order of members.

And lastly, the Chief Secretary suggested that in future the bye-laws of the College should be submitted to the Privy Council for their approval, before they become binding on the College.

The Fellows of the College themselves—constituting the conclave which Sir Michael Hicks-Beach desired to liberalise—rejected this proposition, and decided to stick to the ballot at all hazards, and, therefore, the question of a new Charter has lain dormant for the last twelve months. At length, the Lord-Lieutenant has consented to the proposal put forth by the Fellows that a new order of members, a higher class of licentiates without the privileges of Fellows, should be created, and that consent has been communicated to the Fellows last week in the following letter :—

"Dublin Castle, Feb. 4, 1878.

"Sir,—With reference to previous correspondence, I am directed by the Lord Lieutenant to acquaint you that, as at present advised, His Grace sees no objection to the grant of a Supplemental Charter to enable the King and Queen's College of Physicians in Ireland to institute an Order of Members, on analogous conditions to those prevailing in the Colleges of London and Edinburgh, and also permitting the election of Fellows, by a majority, with Ballot; but as it appears most desirable to substantially increase the number of Fellows, and to provide effectually against the possibility of unreasonable restrictions, His Grace is strongly of opinion that any Charter permitting election by Ballot must be so framed as to abrogate the present restrictive by-laws, and to prohibit any future enactments of like restrictions.

"I am to add that the details of the Supplemental Charter will require careful consideration; but if the College will submit a draft, framed with a due regard to the above-mentioned principles, His Grace will be prepared to consider it, and communicate further with the College on the subject.

"I am, Sir,
"Your obedient servant,
"T. H. Burke.

"To Samuel Gordon, Esq., M.D.,
"President to the King and Queen's
"College of Physicians in Ireland."

It is not easy to see how the wishes of the Lord Lieutenant are to be carried into effect. So far as the establishment of an order of members, and so far as the

election of a Council is concerned, there need be no difficulty, but we cannot as readily understand how the "number of Fellows" is to be "substantially increased" as long as it continues to be within the power and the uncontrolled caprice of a majority of those now holding the Fellowship to forbid absolutely the admission of a single new Fellow. His Grace is prepared to approve "the election of Fellows by a majority with ballot," and yet will not be satisfied unless the Fellows previously bind themselves to forego their right of rejection when the ballot comes to be taken. The very first exercise of the voting powers of the new Charter may be sufficient to prove that the Fellows are not disposed to "substantially increase" their number; and we shall be curious to peruse the Charter which will endow them with individual discretion, and, at the same moment, prevent the exercise of that discretion.

SMALL-POX AND "SUCCESSFUL VACCINATION?"

In the weekly returns of the Registrar-General, ending February 9th, we are informed that the deaths from small-pox were more numerous than they have been since June last. They amounted to fifty-five, whereas in nineteen large provincial towns, with an aggregate population slightly exceeding that of London, not a single fatal case was recorded. This difference is not accidental. There must be something radically wrong in the treatment of the epidemic. Is the Vaccination Act steadily carried out? Have the cases said to be vaccinated been effectively vaccinated? Is the isolation of patients during and after attack carefully carried out? There are hospitals, and yet people die of small-pox in these exceptional numbers.

The number of small-pox patients in the Metropolitan Asylum Hospitals, which at the beginning of October last had declined to 137, steadily increased to 542 on Saturday, 2nd instant, and were 536 on Saturday last; 127 new cases were admitted to these hospitals during last week, against 126 and 146 in the two preceding weeks. The Highgate Small-pox Hospital contained 57 patients on Saturday last; in the six preceding weeks the numbers had steadily increased from 26 to 56.

We have also before us the report of the sanitary committee of the small-pox epidemic, as it affected Islington, of 1876-77, in which report the medical officer of health, Dr. Tidy, justly remarks that there is need of some more efficient legislation in the matter of vaccination. Several months ago we pointed out that the words *successfully vaccinated*, as printed in the vaccination forms, is a very uncertain and misleading phrase, and we suggested that Government should not allow the form referred to, to be filled up unless the arm had "taken" in a certain number of cases. The chief reason why so many contract the disease after vaccination is that either this operation has been imperfectly performed, or that re-vaccination has been entirely ignored. For instance, it would appear that twenty-five per cent. of the children attending the Board schools are imperfectly vaccinated. "At the present time," observes Dr. Tidy, "Government refuses to pay out of the public funds for the re-vaccination of any children under twelve years old who have been once certified as successfully vaccinated. Unfortunately, successful vaccination does not necessarily mean efficient vaccination, and consequently many remain exposed to the contagion of the disease whenever an outbreak of it occurs. With regard to the number of marks that should be taken as proof of a successful vaccination, Dr. Tidy asks: "Is one mark on the arm to be called successful vaccination? I think not; and nothing less than three marks, in my opinion, is." We agree with him; but what is the vaccinator to do? There is not, as there should be, a form for those cases in which the arm has only imperfectly "taken," and which therefore cannot be regarded as successful. The present forms apply only to those cases which have been successful, or in which the operation has been postponed, or which are insusceptible of vaccination. Consequently, if a child is vaccinated, and the arm has only taken in one place, the vaccinator has no alternative but to fill in the form for "successful vaccination," without stating, as he should be directed to state, the number of marks left by the operation. Of course this objection would not be a very serious one were re-vaccination to be more generally practised; and the fact of there being, as there always will be, so many children unsuccessfully vaccinated, is one of the strongest reasons why the operation should be repeated when they have grown up. Dr. Tidy is therefore right in saying that greater facilities must be given, and greater powers extended to the authorities for the purpose of carrying out vaccination, and, we may add, re-vaccination, so that we should reap its full benefit.

Notes on Current Topics.

The Lectures at the Irish College of Physicians.—The Anatomy of the Spinal Cord.

The third lecture of this year's course of annual scientific lectures in the King and Queen's College of Physicians, was delivered on Monday, Feb. 18th, by Dr. Purser. The subject chosen for this and the succeeding lecture, was the anatomy and physiology of the white columns of the spinal cord. It was shown that while the anatomical investigation of the fully developed cord gave little information as to the course of the fibres, the entire white matter appearing to form one whole, embryological investigation demonstrated that the white matter was highly complex, and consisted of seven distinct tracts which differed widely in the time of their first appearance and subsequent development. Four of these tracts were for the most part made up of fibres of the nerve-roots before they finally terminated in the grey substance, and of commissural fibres which connected portions of the grey matter of the cord lying at different levels. The tracts of this class varied in size in different regions of the cord, according to the amount of grey matter, and the number of nerve fibres entering (or leaving) each part.

The three remaining tracts were developed later, and differed from those of the first class in connecting the spinal cord with the brain, and they consequently increased steadily in size from below upwards. 1. The continuation of the pyramids in the cord, which, according

to the degree of crossing of fibres which occurs at the decusssation, have a variable arrangement, connect the cerebrum (cortex and basal ganglia) with the grey matter of the spinal cord, the connection being chiefly with the cells of the anterior horns. 2. The direct cerebellar tract, which lies at the periphery of the posterior part of the lateral columns, effects a communication between the cells of Clarke's column and the cerebellum. And, 3, Goll's column, which appears to terminate in the post-pyramidal nucleus has an uncertain spinal connection. The facts of human and experimental pathology were shown to confirm in a striking manner the results of embryological research.

The Practice of Smoking.

It is always desirable that the medical profession and the lay press should be of one opinion on any question that concerns the health and happiness of the community, and that our more influential and widely circulated newspapers should give as little encouragement as possible to habits which, in the opinion of many, do more harm than good, both as respects the health and morality of the people. A few days ago the *Daily Telegraph* had a long leader on the practice of smoking, which, although taking a very practical and common-sense view of the subject, will nevertheless have a tendency to encourage the practice beyond the limits of prudence and moderation. According to the Annual Report of the Inland Revenue Board, the quantity of tobacco cleared for consumption in 1876 was equal to one pound and seven and a-half ounces for each head of the population. Thirty-five years previously, in 1841, the total came to only fourteen ounces; in 1851, it was seventeen ounces; in 1861, it was nineteen ounces and a-half; and in 1871, it was twenty-one ounces and a-half. Evidently the consumption of tobacco goes on steadily increasing; and we think it is the duty both of the medical profession and the lay press to do all they can to check this rapidly increasing consumption. We cannot say that the article above-mentioned is calculated to effect this desirable object; and if on the contrary our contemporary is rather enthusiastic in its praises of tobacco smoking. "We must," we are told, "do our best to take the facts of life as we find them. Most men smoke. Can it be shown, or even suggested, that non-smokers live longer than smokers. We venture to think not." . . . There is a vast amount of common sense in human instincts. Nine men out of ten will declare that they smoke because it quiets them. Tobacco, in other words, is an anodyne. "It soothes and tranquillises the overwrought nervous centres, and if, indeed, it poisons us, does so with the maximum of comfort and pleasure, and the minimum of inconvenience. In youth, while the heart is still in process of growth, let its use be by all means eschewed. In adult age it is a solace for troubles, a companion in solitude, a narcotic and sedative more potent than ary known to the Pharmacopœia; and there can be, we venture to think, but little doubt that, "thoughtfully taken," it diminishes the worry and friction of existence, while the evidence that it contributes in any sensible degree to shorten life is extremely questionable."

We agree with these observations in the main; and, in a previous article on the subject, we adopted, with certain reservations, a similar line of argument. But, a journal that is read by the million, and is circulated among all classes of society, cannot be too careful to let its readers know that what it says in favour of smoking tobacco merely applies to a very moderate indulgence in this habit. After making several allowances and deductions, it is calculated from the above statistics that among the smoking community the average quantity of tobacco consumed per head does not amount to more than half an ounce per week; and "it can hardly be contended," says our contemporary, "that this quantity is an injurious amount for a full-grown man to consume." Unfortunately, however, the doctrine of averages goes for nothing in questions of this kind. A large number of people may be consuming an almost poisonous quantity of tobacco, while the rest of the smoking public may be keeping far within the limits of moderation; and it is just this baneful habit of excessive smoking, as practised by the former class, which every publicist should make a point of discouraging as much as possible. The medical profession can do much to check the immoderate smoking which is now so universally prevalent, and it is to be hoped that the lay press will take every opportunity of reminding its readers that the immoderate use of tobacco is a habit which can never be indulged in with impunity.

"Beautiful for Ever."

It is a great pity that those fair dames, who are in search of a good complexion, or who are anxious to retain their good looks, should not take more legitimate means of doing so than running after people who make it their business to prey upon the credulity and frailty of human nature. It is surprising that any woman of ordinary education should be ignorant of the fact that the improvement of her personal attractions, so far as they can be improved, depends upon conditions respecting which her ordinary medical adviser can give her the best information. Those little freckles, that dreadful eruption, those untimely blushes, and that sallow, red, or jaundiced tint, which so disfigure her face, are, as she should be told, often the result of a disordered state of the system which, in nine cases out of ten, may be remedied by a judicious course of medical and hygienic treatment. Perhaps, however, we are not altogether blameless in the matter, and may, through our indifference to the petty but very excusable complaints of our fair patients, drive them to those ignorant and unprincipled charlatans who exaggerate the gravity of their symptoms, and frighten them into adopting measures which do a great deal more harm than good. We are too apt to forget that it is quite natural for a woman to attach too much importance to anything that disfigures her, and that the physician who will seriously treat and remove some slight but unsightly eruption from her face will be thought more of than if he had cured her of a pneumonia or pleurisy. We counsel, therefore, our medical brethren to treat the little complaints and foibles of the fair sex with more consideration than they generally do, and not allow them to fall into the hands of those unscrupulous persons who are ever ready to take advantage of their ignorance or credulity.

Medical Reform.

THE *British Medical Journal* says it "has reason to know that the course which the Government will take this session in respect to medical reform is not yet decided." This impression might readily have been derived from the reply of Lord Sandon in the House of Commons, but there seems to be little doubt that the Government is really preparing for action with the purpose of enforcing conjoint examination upon the licensing bodies. If the Eastern anxieties of Parliament were once relieved, we might very probably have a Bill this Session which would be appropriate at the present juncture, inasmuch as the conjoint examination arrangements for England are all but complete. Meanwhile the Medical Council is *more suo*, taking its final doze before the dawn, when it awakes at the end of the parliamentary session to a consciousness, it is expected to do a certain amount of talking each year. As usual it is incompetent to express the feelings of either the profession or the public; and its opinion is, naturally, entirely disregarded by Government. The Council itself, will, indeed, be the greatest difficulty of the Medical Reform Legislators, for even the least respectable of the Scotch colleges is more efficient than the Council, and, therefore, any measure of reform which does not regenerate that conclave *ab ovo*, will be ineffectual and unpopular. If the profession were asked its opinion it would give an unhesitating verdict, that no administrative body could fulfil its functions with less zeal or more obvious incompetency than the Medical Council.

The London Water Supply.

Dr. CHARLES M. TIDY, the Officer of Health, and Public Analyst of Islington, has issued a laborious and very useful statistical report on "The Quality and Quantity of the Water Supplied to the Metropolis during the Past Ten Years." Such a record at the present moment is of more than usual importance to health officers, and the results obtained are free from all mere sentimentalism; and calculated to enable them to arrive at a just conclusion as to the actual measure of river pollution, and its probable influence over public health. Dr. Frankland reports, as the result of his analyses of the waters supplied to the metropolis and some of its suburbs during January, that, taking unity to represent the average amount of organic impurity in a given volume of the Kent Company's water during the last nine years, the proportional amount of such impurity in an equal volume of water supplied by each of the other companies, and by the Tottenham Local Board, was:—Tottenham, 1·1; Colne Valley, 1·1; Kent, 1·7; New River, 3·4; East London, 3 9; Lambeth, 4·5; Southwark, 5·2; Chelsea, 5·2; West Middlesex, 5·9; and Grand Junction, 6·3; the proportion in the Grand Junction water, after filtration through spongy iron, was reduced to 2·2. The water derived by the five companies drawing their supply from the Thames, was again "much polluted by organic matter, and quite unfit for dietetic purposes," although subjected to efficient filtration before delivery. The proportion of organic matter was reduced to about one-third, and the hardness to little more than one-half, of its original amount by filtration through spongy iron. The Lea water, though efficiently filtered by the New River and East London Companies, was considerably polluted by organic matter in solution. The waters supplied by the Kent and Colne Valley Companies, and by the Tottenham Local Board, furnished the only samples of good water examined during the month; drawn from deep wells in the chalk, these waters were of the usual excellent quality.

Contemplated Change in the Constitution of the India Medical Service.

IT has long been known that a measure to abolish the double medical administration of the British and India Medical Services has been incubating in India. The *British Medical Journal* says it has reason to believe that this measure has been for some time before the authorities at the India Office, and that ere long the new scheme will be published. No one can deny that, on the face of it, it is absurd to have one set of medical advisers for the civil and military administrators for white and another for black troops, as if the general principles of sanitary science were so essentially different for the two races that separate experts were required to expound them. Our contemporary believes that all the medical officers of the India services will be called on to elect whether they will serve in a civil or a military capacity. The civil medical administration will be placed under officers selected exclusively from the India services. Those who elect to serve in the army will, as a matter of course, be under military medical officers selected entirely from the two services, British and Indian; and the troops, without distinction of race or colour, will be under one sanitary authority.

Deaths of Note in France.

THE profession in France has, like ourselves, to deplore the loss of several eminent men from its ranks, notably of members of the Académie des Sciences. Last week we chronicled the decease of that transcendant physiologist, Claude Bernard; we have now to record the death of Professor Becquerel, who for nearly fifty years was connected with the Academy as Professor of Physics, &c. Yet another in the person of Dr. Regnault, Professor at the College of France, the Polytechnic, and Director-General of the Imperial Factory at Sevrès. The death of his son, and the scientific loss of his apparatus, manu scripts, &c., during the Franco-Prussian war, brought on paralysis, from which he has just succumbed, at the age of 67. Names of European reputation, such as Barth, Bouvier, Caventou, Dolbeaw, Hervez de Chegoin, de Kergaradec, Demarquay, and Berthier, have also to be added to the list of the recent dead; and lastly, the brilliant lecturer and surgeon, Professor Hirtz, who, until the Franco-Prussian war, occupied the principal chair at the Faculty of Medicine, Strasbourg; on the annexation of Alsace and Lorraine, his patriotism induced him to throw in his fortunes with the French nation, and to take up his residence in Paris, where he has just died.

THE biennial dinner in aid of the Funds of the National Hospitals for consumption at Ventnor, was given in London on Wednesday last, the Earl of Carnarvon occupying the chair. The pecuniary position of the Hospital is satisfactory.

State Funeral of Claude Bernard.

STERNE'S oft-quoted axiom, "they order this matter better in France," has just received a happy illustration, in honouring the remains of her eminent *savant* Claude Bernard with a public funeral. Would that the same principle were adopted a little oftener in our own country! On the proposition of the Minister of Public Instruction, the Chamber of Deputies and the Senate passed the following resolutions:—The President of the French Republic decrees: 1. That the obsequies of Claude Bernard shall take place at the expense of the State. 2. For this purpose a sum of ten thousand francs is placed at the disposal of the Minister. 3. The expense to be provided from the general funds of 1878.

Gambetta thus expressed himself on the proposal of the Government: "Gentlemen, in the face of such an irreparable loss, there can be but one sentiment animating every member of this assembly. (Approbation.) Scientific France can show to the world many men of talent, many luminaries, but I may say that the light which has been extinguished can not be replaced. (Applause.) Claude Bernard did not only exist for the scientific circles of France, but for the whole world. He was recognised as the inspirer and as the most competent guide in scientific research. In the polemics of science all the world paid him this homage, that he was never the slave of a party, or of a system, or of personal passion. Gentlemen, I shall not pronounce his eulogium; more authorised voices, as those of his colleagues and friends will discharge that duty. We salute the entrance of Claude Bernard into immortality." (Vociferous applause.)

A Jury of Matrons.

THE effete folly of submitting an issue upon which hung the life or death of a prisoner, to the arbitration of a jury of a matrons, was again recently perpetrated, in accordance with the law, at Chester. A prisoner, named Heeson, was found guilty of having poisoned her mother and two children, and pleaded pregnancy as a reason why sentence of death should not be passed. Thereupon, in obedience to the law, enacted in times when no one knew any better method of inquiry, a jury of old women who were loitering about the Court was assembled to inquire as to the truth of the prisoner's plea. The gaol surgeon was ordered to assist this astute and highly informed tribunal, with his opinion, and it being decided that the prisoner was really pregnant, her execution was deferred. It appears that there are doubts as to the legality of employing the medical man at all, but as the judge thought it right to strain a point in order to arrive at truth, it may, we hope, encourage the judge on the next similar occasion to dispense with the jury of matrons altogether.

Creosote in the Treatment of Phthisis.

MM. BOUCHARD AND GIMBERT have recently revived the treatment of phthisis by the above named remedy. Discovered by Reichenbach in 1830; Migniat-Breschet-Grandjeau applied it in phthisis pulmonalis, but though it was vaunted as a specific, it did not maintain its character. MM. Bouchard and Gimbert employ a special preparation of pure, colourless creosote, produced by distillation of wood tar. The following formulæ are used:—

Creosote Wine.—Pure creosote 13 grammes, 50; tinct. gentian, 30 grammes; alcohol, 250 grammes; Malaga wine, q.s. to make a litre. Dose—From two to four spoonfuls in a glass of water daily.

Creosote Alcohol.—Creosote pure, 3 grammes, 50; alcohol, 125 grammes; water, 126. Dose—One tablespoonful daily, half an hour before meals, in half a glass of water.

Creosote Oil.—Cod liver oil, 300 grammes; creosote oil, 2 to 4 grammes. Ordinary dose.

Death of Dr. Peaslee.

WE regret to learn from the *New York Medical Record* that the distinguished ovariotomist, Dr. Edmund Randolph Peaslee, died in New York on Jan. 21st, within one day of completing his sixty-fourth year. The immediate cause of death was pneumonia. Dr. Peaslee was one of the most eminent teachers, authors, and operators, whose works have graced the annals of American surgery. His treatise on Ovarlotomy was the crowning effort of his life, and will remain for a long period the best work on the subject in any language. By his death American surgery has lost one of its ablest exponents—Bellevue Hospital Medical College a teacher whose fame extended over two continents, and afflicted humanity one of its greatest benefactors.

The Will of the late Dr Blundell.

THE will and codicil (dated April 11th, 1857, and March 27th, 1876) of Dr. James Blundell, formerly of 1 Great George Street, Westminster, but late of 80 Piccadilly, who died on the 15th ult., was proved on the 29th ult., by George Augusta Frederick Wilks, M.D., the nephew, and Samuel Frederick Noyes, the surviving executors, the personal estate being sworn under £550,000. The testator leaves to his sister, Miss Mary Blundell, an annuity of £800, and all his furniture, plate, pictures, household effects, horses, and carriages; to his half-sister, Miss Ann Blundell, an annuity of £250; to his nephew, Bezer Blundell, £14,000 Consols; to his nephew, Dr. Wilks, all his freehold, copyhold, and leasehold estates, and £35,000 Reduced Bank Annuities; to the London Hospital, £500; to St. Mary's Hospital, Paddington, £250; and there are other legacies and annuities to relatives, friends, and servants. The residue of his personality is given upon trust for his niece, Mrs. Noyes, and her children.

The Unhealthiness of Dublin.

AT the last meeting of the Executive Committee of the Dublin Sanitary Association, it was announced that the number of patients with small-pox in Cork Street Fever Hospital had increased to 43, of whom 7 were admitted within the last twenty-four hours. Attention was directed to the Registrar-General's returns, from which it appeared that the death-rate for the past week was 34·2 against 29·2, the average rate for the past ten weeks. The zymotic death-rate was 5·1 as compared with 3·9, the zymotic rate for three large English towns. The deaths from these diseases included 6 from small-pox, of whom 2 had never been vaccinated; two others said they had been, but no mark could be found, and in only one was a mark found. There were also 9 deaths from measles, and 6 from fever.

Pasteur on Vibrios.

At the meeting of the Academy of Medicine, Jan. 21, 1878, Pasteur communicated a note on the question of septicæmia for the consideration of surgeons. The vibrios of septicæmia are essentially anæroliotic, the contact of atmospheric oxygen kills them, when, on the other hand, they remain *in vacuo* or in a medium of carbonic acid, they are transformed into germs which the air does not kill. But these germs do not develop in the air, or in oxygen; for their further evolution, carbonic acid is necessary.

Death of a Miser.

An eccentric individual named John Rhodes, of Hounslow, was buried on Monday. Although possessing immense wealth, he dressed like a tramp, and was exceedingly parsimonious, often denying himself the common necessaries of life. He has left the greater portion of his fortune, amounting to £100,000, to various metropolitan charities. Mr. Rhodes, who was a chemist in early life, was nearly 80 years of age.

How to Make "Genuine French Brandy.'

The *American Journal of Pharmacy* gives the following formula for making a prime article of French brandy: "Take of common alcohol and water, each two quarts; mix, and add nitro-benzole, half an ounce."

University of Dublin.

The Academic Council have resolved that the Medical and Surgical Travelling Prizes shall be amalgamated, and have requested the professors of the Medical School to report whether the examination for the Travelling Prize shall be held in alternate years in medicine and surgery, or whether it shall be held each year in the two subjects combined.

Daniels come to Judgment.

At an inquest held recently at Harpur Hill, Lancashire, it was found that only four of the jurymen, when they were requested to append their signatures to their verdict, could not write.

We understand that the Medical Department of the Army is engaging the serious attention of the Secretary for War; and that a scheme will shortly be propounded, which, it is to be hoped, will remove the objections young men have to join

Dr. Engelmann, a Prussian refugee, celebrated for political misfortunes and scientific acquirements, recently died in exile at Brussels. During the political disturbances at Berlin in 1848, he was condemned to death, but succeeded in escaping to Belgium. Dr. Engelmann was an officer of the Turkish Order of the Medjidiè, and a Knight of the Order of Merit in Saxony, as well as a Red Cross Knight of Prussia.

It having been determined to erect another branch of the Birmingham General Dispensary, at Ladywood, Mr. John Carter, M.R.C.S., has given a donation of £100, as the nucleus of a building fund; should the project not be carried out in five years, the donation is to revert to the general fund.

A higher death-rate was prevalent last week in London, than in any corresponding period since April last. The deaths from small-pox were, however, less than the previous week by eight, whilst those from whooping-cough increased alarmingly; 124 deaths resulting from this disease.

THE METEOROLOGICAL SOCIETY OF GREAT BRITAIN.

The usual monthly meeting of this Society was held on Wednesday, the 20th inst., at the Institution of Civil Engineers, Mr. C. Greaves, F.G.S., in the chair, when Dr. Tripe, Medical Officer of Health and Food Analyst for Hackney, read a paper on

THE WINTER CLIMATE OF SOME ENGLISH SEA-SIDE HEALTH RESORTS.

The places selected were Scilly, Torquay, Penzance, Guernsey, Barnstaple, Ventnor, Llandudno, Ramsgate, and Hastings, and the climatic features of each were compared with those of London. The results of this discussion may be briefly summed up as follows, viz.—the mean daily winter temperature of these sea-side places, and especially of those situated on the coast of Devon and Scilly is higher than at London; the mean daily maxima and minima are also higher, and especially the latter, so that the daily and monthly ranges of temperature are smaller; the mean humidity is less; the general direction of the wind about the same, but the number of rainy days and the rainfall are greater at the sea-side. As regards the wind, therefore, the chief point to be especially noticed is amount of shelter afforded by high land, as at Ventnor, and especially of protection against the stormy and cold winds which ordinarily prevail at the end of February and in March. The soil also should be considered, as heavy rains at gravelly and chalky places are not so objectionable as on clayey ground. The discussion on this paper was adjourned until the next meeting, which will be held on March 20th.

The following were elected Fellows of the Society:—W. C. Baker, W. Berridge, W. M. Burke, Rev. J. A. P. Campbell, Prof. J. Eliot, Lieut. C. S. F. Fagan, C. H. Holden, Prof. H. J. S. Smith, Capt. W. Watson, and C. Woollett.

Correspondence.

MEDICAL WOMEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your correspondent, "Fair Play," argues the cause of the lady students upon false issues, and, by assuming reasons which, I believe, do not actuate any considerable number of medical men, he does an injustice to the good sense of those who, upon totally different grounds, discourage lady-doctoring. No unprejudiced thinker now denies to individual women the possession of mental faculties immeasurably superior to those of the general run of male students. I might answer that "one swallow does not make a summer," but prefer to admit, as I conscientiously believe, that the ladies are, when properly educated, and firmly devoted to the study and practice of medicine, entirely capable of filling the modest *rôle* of general practice. But, Query, is one out of ten of them suitably educated to that object in childhood? Or is one out of 100 "firmly devoted to the study and practice of medicine." Surely it is no discourtesy to ladies in general, to say that they are not brought up to think on grave subjects, or to earn their living in professional competition, but are given just enough knowledge to make them attractive to the average (often *very* average) husband. What further proof is necessary than a comparison between the miserable sham education thought sufficient for daughters, and the hard practical teaching considered indispensable for sons, to convince us that marriage

is the *ultima ratio* of the female population? I am conscious that this argument should not go to exclude from medical practice the truly rare specimens of femininety who bring to the study of medicine a sound masculine education and a determination to succeed in practice, untinctured by the hope of succeeding sooner or later in matrimony. If such unique specimen exists, it would be as cruel and stupid to hinder her growth, as it would be to shoot and stuff a live Dodo; and the great majority of medical men, while they feel convinced that, in the abstract, professional success is impossible to a section of the community who are not educated to it, and who pursue it only as a temporary expedient, would not, if they could, refuse "fair play" to those ladies who think otherwise.

The object of this letter is, however, to deprecate what I must be rude enough to call the puerility of your correspondent's argument. He says :—

"Does Smith, who objects to associating in a lecture-room with a highly-educated lady, equally object to his receiving his matutinal glass of beer and smiles from the maidens at the *restaurant* patronised by the hospital? A woman behind the bar is tolerated and often idolised by the same young fellow who is ready to insult Miss. S. in the lecture-room. Strange perversion of the male intellect, caused by custom and habit!"

It is not the first time that I have heard such nonsense as this imported into the discussion. It might be hoped that those who write on the subject, would see that a barmaid, who is an admirable work of nature and art behind the counter, would hardly be in her proper place in company with a crowd of students at a lecture on Hernia. To me, it is quite conceivable that the old heads amongst medical teachers should object to the intrusion into their classes of an element almost as unfavourable to serious study as a Punch and Judy show would be; and it is also quite conceivable that a medical student may feel that, however charming the ladies may be in unprofessional association, the amative society of a "sweet girl-graduate" is barely consistent with business, and would make him (if not the lady) decidedly uncomfortable on many awkward professional occasions.

I, therefore, urge that lady students should learn their profession in each other's company, and that, having learned it as thoroughly as male pupils, they should have every fair play in qualification and in practice. If the demand for lady doctors (which they allege) really exists, there will be an ample *clientele* of students to maintain their own school and their own wards in hospitals. If the demand be insufficient for this, it can hardly be asserted that the public really wants "lady doctors."

Yours, &c.,

HIBERNICUS.

A PLUM FOR THE ANTI-VIVISECTIONISTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—No doubt Mr. George R. Jesse, "Hon. Sec., Treasurer, and Member of Council of the Society for Total Abolition of Vivisection," and who takes *no* notice of "uncomplimentary remarks," would find amongst the *humane* spectators of the following noble entertainment some of the most strenuous supporters of the Society of which he is the secretary, &c.

Here is the story of what, we suppose, should be described as a "splendid day with the hounds." "Yesterday, we read, Her Majesty's staghounds met Lord Harkwicke, the master, and a very large field, at Gerrard's Cross, five miles from Uxbridge. A favourite stag was uncarted, and, after running almost in a ring, it took to a sheet of water in Bulstrode Park, the seat of the Duke of Somerset, and was literally torn to death by the hounds." A spectacle for the gods, surely! Yet our noble huntsmen would probably resent with scorn the imputation that they could witness a Spanish bull-fight.

This extract is from a contemporary which professes to be a great friend to the "Medical students or medical roughs?" who figured at the Metropolitan Tabernacle last week during a meeting held there in the cause of sham humanity, and against the advance of science and investigation into the laws of life.

I am, &c.,

EQUIVOCAL HUMANITY.

DR. OFFENBERG ON RABIES AND HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Enclosed I send you a copy of the *All. Med. Centr. Zeitung*, No. 2, Jan. 5, 1876, in which there is an account (taken from the *Deutsche Zeit. fur Practische Med.*) of the case of hydrophobia cured by me by means of curara.

You will now agree with me in my assertion that the report of the case of Dr. Polli (as in MEDICAL PRESS AND CIRCULAR, June, 1877) was only a translation of the above-mentioned case of mine, and that in reality there does not exist a particular case cured by Dr. Polli.

The difference between the two reports consists only in the statement of the age of the patient and in the name of the attending doctor, whilst all other particulars completely agree.

When I first communicated with you (Jan. 7) I also wrote to Mr. George Fleming, the editor of the *Veterinary Journal*, enclosing the *Deutsche Zeit. für Practische Med.*, No. 52, 1875, in which the account of my case first appeared.

I have not heard Mr. Fleming's opinion on the subject, or whether he considers a rectification necessary.

The "Special Report" of your commission which is to appear in book form, I have ordered through Hirschwald's Library in Berlin, and I rejoice thus to be able to obtain it, for the fragments I have read in single numbers have greatly interested me.

Yours obediently,

Wickrath, Rhenish Prussia, Feb. 14, 1878. OFFENBERG.

*** The difficulty of arriving at facts is very great, and we have felt this whilst engaged in our "Report on Rabies." We have, in the reputed case of rabies with Dr. Polli's name, a very striking illustration of this truth, for when we thought we had a fact, that there was a case of recovery, Dr. Polli, it now seems he is only a translator, and thus the case reported as cured by curara by Dr. Polli turns out to be the same one originally reported by Dr. Offenberg.

Thus, two cures have been made out of one. In June, 1877, we gave Polli's case publicity, taking it from *Le Paris Médical*. Since that time it has been copied into numberless journals: *The Lancet*, *The Medical Times and Gazette*, &c., the daily papers of England and America. We have traced it through *Le Paris Médical* to Dr. Fanos, *Journal of Surgery*, No. 49, where it was inserted from the Annals of the Medico-Chirurgical Society of Liège, who had obtained it from the *Annali dal Dr. G. Polli*. Other references given were the *Gaz. Med. Ital. Prov.*, Feb. 26, 1876, and the *Allg. Med. Berlin Centr. Zeit.*, No. 2, Jan. 5, 1876.

After doubling and twisting like a hunted hare we have thus traced it back to its original form. But there we find no mention of Polli, and we have the following simple statement :—

OFFENBERG—*Lyssa humana mit Curare erfolgreich behandelt.*

We have made these facts known in the interests of science and justice. If there is a Dr. Polli we hope he may come forward and clear up any remaining doubts there may be about the facts. We cannot wonder at the numberless mistakes that are made by the lay press. We have found that one case of hydrophobia does duty for nearly a dozen, for it is copied from paper to paper, mistakes in name, in age, and locality unintentionally, by what are termed "printer's blunders," creeping in.

The vitality of error is very great, but we hope the journals which inserted Polli's name will also insert an announcement of the new facts which have come to light in reference to it.—ED. M. P. & C.]

PROSTITUTION AND THE GENEVA CONGRESS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Kindly allow me to remark that when a man is hanged it is with the consent of a jury of his equals, under the direction of a skilled judge, and on the testimony of witnesses, who depose to facts, not suspicions, and who are punishable for falsehood. It is revolting that he should be hanged, but while hanging is the punishment for murder, and he has a fair trial, no one can complain.

Now, a girl accused of unchastity, by a police spy paid to accuse, is subjected to a periodical revolting outrage on his bare suspicion, without judge, jury, trial, or conviction, and, in the great majority of cases, without even investigation, and damned by the eternal infamy of registration, although she has

committed no crime, is not even suspected of any legal offence whatever, is absolutely free from disease, and is not proved to be unchaste. Why should a woman be punished *before conviction*, any more than a thief or a murderer? If you will make prostitution a crime, accord to the prostitute the same legal safeguards that are accorded to other criminals, and treat both sexes alike. No one can complain, but the present system would disgrace a despotic monarchy.

THOS. WORTH, M.R.C.P.

[We quite agree with our correspondent, that it would be a disgraceful thing were women who are innocent, chaste, and free from disease, to be subject to the inquisitorial proceedings sanctioned by the Contagious Diseases Act. But is that the case? We say certainly not, and our correspondent gives no proof to the contrary; we have only his *ipse dixit* that "women absolutely free from disease and not proved to be unchaste" are subject to the Act. Were any such cases to happen, the opponents of the Act would only be too ready to make them public, but the fact is a woman is never subject to the treatment Dr. Worth complains of until she has been proved to be a prostitute.—ED. M. P. and C.]

THE OXFORD SCHOOL OF MEDICINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I thank you very much for the excellent article in your issue of the 6th inst., on the "Lost Medical School." The original letter, and the two *British Medical Journal* articles, on which your remarks were founded, are disgraceful. 1. There *never* has been a medical school in Oxford in *any sense* of the word. 2. No single man has done more than Dr. Acland to raise the character of the Oxford medical degree, and in the work thus done Dr. Rolleston has had a very great share. 3. The number of medical graduates from Oxford is steadily increasing—last December we passed eight. 4. Large numbers cannot be turned out from Oxford unless the present high standard be lowered, and time occupied be greatly reduced. 5. It is an extremely difficult question, not to be decided off-hand by imperfectly informed persons, whether it is desirable, either partially or completely to set up a medical school in Oxford where there never has been one, and where one has not sprung up as in other towns, spontaneously from the need being felt on the spot.

Yours very truly,
M.D., Oxon.

Leeds, February 20th.

Literature.

SCIENCE FOR ALL.

MESSRS. CASSELL'S latest venture, of which the two first numbers lie before us, is a most admirable exponent of popular science, and it differs from other efforts in the same direction in the method by which it conveys the information which it contains. Instead of taking for its text a certain branch of science and saying as much as can be said respecting a very large subject (necessarily very little when an extensive scientific field has to be transversed in a few pages), each article is devoted to some every-day subject of observation, such as a leaf, a piece of sponge, or a bit of limestone, and an entertaining and instructive sketch is given on it. In the two numbers before us we have "The Man in the Moon," by Proctor; "A Piece of Limestone," by Alleyne Nicholson; "Hunger," by Robert Wilson; "A Fallen Leaf," by Robert Brown, F.L.S.; "Ice, Water, and Steam," by J. E. H. Gordon, of Caius College; "A Highland Glen," by Robt. Brown; "Whirlpools and Whirlwinds," by W. Ackroyd; "The Light of the Future," by T. C. Hepworth; "The Chemistry of a Brewer's Vat," by W. B. Ferguson, of Christ Church, Oxford; and "A Piece of Sponge," by J. Murie, M.D.

The parts are extremely well printed and beautifully illustrated, and the names of the authors who contribute to their pages are sufficient guarantee for the value of their contents. The publication does great credit to the Messrs. Cassell.

One Appointment subsequently added,

War Preparations.—Amongst several orders for hospital service in the British Army which have just been made are some hundreds of ambulance stretchers and several thousand sets of hospital bedding. The date for the delivery of these articles is given as the first week in March if possible.

NOTICES TO CORRESPONDENTS.

JACKSONIAN.—The subject selected by the Council of the Royal College of Surgeons for competition for the next Jacksonian Prize is, "Glaucoma; its Causes, Symptoms, Pathology, and Treatment." The award will be made at Christmas.

HUNTER.—The subject for the John Hunter Prize, value 50 guineas, to be awarded in 1879 by the Council of the Royal College of Surgeons of England is, "The Anatomy and Physiology of the Third, Fourth, and Sixth Nerves, as illustrated by observation and experiment in Health, and by reference to the Effects of Injury and Disease."

ECCENTRIC, REFLEX, OR IRRITATIVE ALBUMINURIA.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—As I did not see the proof of my short paper on "Eccentric, Reflex, or Irritative Albuminuria," allow me to make a few corrections in that paper as it appears in your number of Feb. 20, 1878. The following passage should read as I thus transcribe it:—

"I am confident many cases will be met with of this form of albuminuria, namely, reflex, eccentric, or irritative; and that, if recognised, we may save our patient, if overlooked, we may let her slip from life to death.

"I think that puerperal albuminuria—even coupled it may be with convulsions—arises rather from the great nervous disturbance, especially the local; and from the *consequent* renal congestion and the condition of the entire renal system—such as I have described in the *Prac-*

titioner—than from that condition of the blood which obtains in, and is, we may say, natural to the puerperal state. Here this latter (the condition of the blood dependent on the puerperal state) the sole factor of the albuminuria and convulsions, albuminurial puerperal convulsions would, I apprehend, occur more frequently, the puerperal blood-changes being always present, whereas, the great nervous disturbances—general and local—do not take place in all women: those, the subjects of them, being particularly prone to the affection I describe.

"I consider these cases of puerperal albuminurial convulsions to be of a truly eccentric, irritative, or reflex origin, the local or uterine disturbance being the originating agent."

Yours, &c.,

9 Lupus Street, London, S.W. G. DE GORREQUER GRIFFITH.

SMALL-POX AT LINCOLN.—This disease has introduced itself in a case of a most malignant nature. The deceased, a servant at an hotel, died within three days of the attack. A chemist had seen the deceased, but gave, as *his opinion*, that she was only suffering from chicken-pox. A medical man was called in a few hours before death took place, and at once diagnosed the disease, but death ensued before his instructions were carried out. The case caused considerable excitement in the city, and the coroner, in order to satisfy the public clamour, held an inquest on Thursday. Deceased had voided a two months' fœtus whilst in bed.

DEARTH OF ARMY SURGEONS AT THE CAPE.—Inquiries having been made of us in reference to an alleged demand for surgeons at the Cape at salaries of £2 2s. and £5 5s. a day, we have sought information on the subject and cannot ascertain that there is any substantial truth in the report.

OBSTETRICAL SOCIETY OF LONDON.—Wednesday, March 6th, at 8 p.m., Specimens and Instruments: Dr. Hayes, Tube for Intra-Uterine Injection of Solution of Perchloride of Iron. Dr. Galabin, Metrotome. Dr. John Williams, "Uterus with portion of Placenta, three weeks after Labour." Papers: Dr. Matthews Duncan, "On Traction by the Lower Jaw in Head—last cases." Dr. Geo. Roper, "Case of Protracted Labour in which the Forceps was typically indicated."

DR. P.—An inquest would undoubtedly have been the proper course; but it is probable that as you had been attending deceased for the complaint from which he died the coroner considered an inquest unnecessary.

A STUDENT OF CHARING CROSS.—Your letter, received as we were going to press, is not one which could be answered off-hand. You have, moreover, omitted to comply with our rule in not sending your name, not necessary for publication, but as evidence of the *bonâ fides* of the writer.

ANOTHER CURIOSITY OF MEDICAL LITERATURE.—In the *Irish Times* we find the following advertisement:—

TO INVALID GENTLEMEN.—A respectable young Man, who understands the care and treatment of the above, wants a situation; understands the administering of medicine; *can compound, and, in the absence of a medical man, could prescribe;* could make himself generally useful as he understands general indoor work.

It was hardly necessary for the "respectable young man" to advertise himself as "generally useful." The retainer who "understands general indoor work," and can compound and prescribe is, indeed, what the theatrical papers call a "general utility." But, perhaps, the general indoor work is a euphonism for a knowledge of the uses of purgatives.

THE SARTORIUS MUSCLE.

THE following is one of the rhythmical *memoriæ technicæ* given in the *Students' Journal*:—

The Sartorius muscle's the longest one sees,
From pelvis to tibia extends;
From outside to in, on the side of the leg,
O'er the thigh, right across, it now bends.

It lies in a hollow by adductors formed,
With extensors, I think you will find
The fibres which form it are longer by far
Than any you'll see of the kind.

From the upper anterior spinous process
Of the ilium its origin see,
By an aponeurosis inserted, it is
On the tubercle's side, 'neath the knee.

An expanded insertion it is, and placed on
The upper and internal face
Of the tibia, so for an inch and a half
Its insertion we easily trace.

A SERIOUS WANT IN THE ARMY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Only a few years since I mentioned to a War Office official, who means well, but knows really nothing of the value of the medical profession, that the day would come when the *improved system* of *our* Army Medical Department must fail. I have been a regimental officer, also a staff officer in the good old times, when, as you mentioned in your last, "the service was popular with the medical profession." Those times must come back again if the Government do not want the Medical Department to be nobody's child, and its members treated as outside dogs.

Yours truly,

A LATE STAFF-SURGEON.

A MODERN GIANT.—The Newcastle-on-Tyne correspondent of the *Lancet* gives some particulars as to Mr. William Campbell, landlord of the "Duke of Wellington," in this town. Campbell boasts of being the largest subject in Her Majesty's realms, standing 6 feet 4 inches in height, and weighing over 52 stones. He measures round the shoulders 96 inches, round the waist 85 inches, and round the calf of the leg 35 inches. He was born in Glasgow in 1856, and has not quite attained his twenty-second year; was one of a family of seven children, none of whom beside himself are of more than ordinary proportions. His father was of average weight, although he stood 6 feet 2 inches high; his mother was rather under the average height and weight of women. Campbell stated that from birth he was remarkably stout, and that at nine months old he weighed 4 stones, at 10 years of age he weighed 18 stones, and he has gone on increasing since then, and it is with difficulty he keeps at his present weight. He was brought up as a printer, but was compelled from his extraordinary size to give up his occupation. His powers of locomotion when well were considerable, taking into account his huge bulk; his appetite was not more than an average one, and, although not an abstainer, he was moderate in his use of alcoholic drinks.

VACANCIES.

Cork District Lunatic Asylum.—Assistant to the Resident Medical Superintendent. Salary, £110, with apartments and allowances. Election, March 1.

Glamorgan Infirmary, Cardiff.—House Surgeon. Salary, £100, with board, &c. Applications to the Secretary on or before March 11.

Hertford General Infirmary.—Resident Medical Officer and Secretary. Salary, £100, with board. Applications to the Chairman of the Board by the 6th prox.

Kensington Dispensary.—Resident Medical Officer. Salary, £125. Also a Dispenser. Salary, £70. Applications to Mr. J. Batten, 6 Campden Hill Terrace, W.

Salford Union.—Assistant Medical Officer. Salary commencing at £130 with apartments, &c., in the Workhouse. Applications by March 4th, to the Clerk to the Guardians, Union Offices, Salford, Manchester.

South Charitable Infirmary, Cork.—House Surgeon and Apothecary. Election, March 8. (See Advt.)

Stockton Hospital.—House Surgeon (non-resident). Salary, £200. Must give his whole time to Hospital and reside close to the Institution. Applications to the Secretary at the Hospital, Stockton-on-Tees.

West London Hospital, Hammersmith.—House Surgeon. Furnished apartments, &c., with an allowance of £80 in lieu of board. Testimonials, &c., to the Secretary by the 2nd prox.

APPOINTMENTS.

BATTAMS, J. S., M.R.C.S.E., appointed a Junior resident Medical Officer to the Royal Free Hospital.

CLIPPINGDALE, S. D., M.B., House Surgeon to the London Hospital.

DEVIS, C. J., M.R.C.S.E., House Surgeon to the Bootle Borough Hospital.

MOORE, N., M.D., F.R.C.P.L., an Assistant Physician to the Metropolitan Free Hospital.

NEWTON, J., M.R.C.S.E., Junior Resident Medical Officer to the Carlisle Dispensary.

ORMEROD, J. A., M.B., M.R.C.P.L., an Assistant Physician to the Metropolitan Free Hospital.

RYAN, J., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer, &c., for the Grean Dispensary District of the Tipperary Union.

SOUTHAM, F. A., M.A., M.B., F.R.C.S.E., House Physician to the Royal Infirmary, Manchester.

WHITE, R., M.B., L.R.C.S.I., Medical Officer, Public Vaccinator, &c., for the Whitechurch Dispensary District of the Cork Union.

Marriages.

HEMMING—STRICKLAND.—On Feb. 12, at St. James's, Norland, W., W. Douglas Hemming, M.R.C.S., of Notting Hill Terrace, to Harriet Isabella, daughter of Major Strickland.

OWENS—STEWART.—Feb. 14, at Dublin, John Owens, L.R.C.S.I., L.K.Q.C.P.I., to Frances Adelaide, youngest daughter of the late Lorenzo Moore Stewart.

Deaths.

BOOTH.—On Feb. 16, at his residence, 13 Lower Sherrard Street, Dublin, Daniel Booth, L.R.C.S.I., L.R.C.P.E., aged 36.

BROWN.—On Feb. 14, at Dunfermline, Robert Brown, M.D., aged 67.

CLARKSON.—On Feb. 13, at Knowle, Josiah Clarkson, M.R.C.S.E., aged 60.

INGHAM.—On Feb. 14, at Bath, Dr. Charles Thomas Ingham.

PATRICK.—On Feb. 10, at Carron Park, Larbert, David Patrick, M.D., aged 77.

POTTS.—On Feb. 20, at 14 Woburn Square, London, Selena, widow of T. B. Potts, M.D., L.R.C.S., of Cranbourn, Dorset, aged 62.

RYAN.—On Feb. 8, at New Pallas, co. Tipperary, John Ryan, M.R.C.S. aged 57.

THE CAUSE OF THE CUPPING OF FARRE'S TUBERA CIRCUMSCRIPTA OF THE LIVER. (a)

By B. WILLS RICHARDSON, F.R.C.S.,
Surgeon to the Adelaide Hospital, Dublin.

A FEW months ago I obtained from a liver beset with medullary cancer, a very characteristic specimen of one of the cupped tubers of Farre, from which I cut many sections, after it had been frozen, with the view of corroborating, or otherwise, the statement of some pathologists as to the cause of this tuber being umbilicate.

As far as my observation goes, it to some extent confirms the opinion set forth on this point in a note in Frerichs' work on the liver.

Speaking of cancer of the liver, Frerichs remarks that its development, "as is the case in every other part of the body where the disease is met with, is limited; whenever the disease has existed for a long time it is found to exhibit traces of decay and retrograde metamorphosis. These changes consist in fatty degeneration, as well as atrophy and shrivelling of the cancer. The cells lying in the meshes of the fibrous stroma become filled with oil globules, and present a white opaque appearance, imparting to the morbid growth a reticulated aspect, or nodulated masses are formed, by large groups of cells at one place becoming atrophied. The fatty cells may ultimately become disintegrated into an emulsive fluid, which gradually undergoes absorption. At those places where this happens, and they are mostly the central portions of the tumours, the fibres of the reticulated stroma are densely aggregated, the meshes become smaller, and ultimately there remains only a firm cicatrix-like tissue, from which no cancer-juice can be pressed out."

"The outer surface of the cancerous nodule," he goes on to say, "is drawn in and depressed in an umbilicated manner, owing to the contractile fibrous tissue gradually becoming more and more shortened. A section made through a depressed nodule of cancer of the liver presents the following appearances:—

"In the centre of the nodule an umbilicated depression is observed, and beneath this the fibres of the reticulated stroma are closely compressed; the meshes at this place are contracted and partly destroyed, whilst those towards the periphery of the nodule are large and filled with cancer-cells."

"These changes," he further observes, "have been regarded as indications of the commencement of cicatrisation and cure of hepatic cancer. Oppolzer and Bochdalek have published observations of cases in which they believe they have traced, both clinically and anatomically, the process of spontaneous cure of cancer of the liver. There can be no doubt that the condensation and shrivelling of the cancerous nodules," . . . . "are, in many cases, to be looked upon as a local retrograde metamorphosis, or, if one prefers the term, as the commencement of cicatrisation; but this process is very different from an actual cure of the cancerous disease. Together with the retrograde change going on in the centre of the cancerous nodule, a progressive development is observed at the circumference, which proved that the morbid process is not extinguished, but only locally destroyed."

I am by no means prepared to admit that the condensation of the axis of the tuber is the result of cicatrisation, and for the simple reason, that the cupping is observed in young tubers. Indeed, in a note on the page of the text of Frerichs' where the observations on the cupping terminate—whether this note is by the author or the translator is not, however, stated—a more probable view is, to my mind at least, taken of the cause of the cupping. The note states that "the umbilicated depression on the outer surface of hepatic cancer is not always produced in the manner above-mentioned. It is often observed in young nodules, in which no appearance of retrograde metamorphosis can be detected. I attribute," the writer continues, "the appearance, under such circumstances, to the greater contractility of the older connective tissue of the central portions of the nodules, and to the diminution

(a) A paper read before the Surgical Society of Ireland.

of the cancer-juice, in consequence of the supply of blood being lessened by the growth going on at the circumference." (*a*)

The drawing of a vertical section of a tuber given by Frerichs to illustrate his description of the cause of the cupping, represents merely a closer meshing of the tissue in the vertical axis of the tuber. Whereas in my sections made at right angles to the same axis, all of which are of extreme tenuity, the centre of each is formed of condensed tissue, so that it is evident that the axis was formed of a cord of fibrous tissue, which as it were tied down, and prevented the centre of the tuber from rising.

On the other hand, there is a loose alveolar tissue surrounding this axis, which, when charged with cells, forced the circumferential portion of the upper surface of the tuber above the level of the centre, which was thereby depressed, and hence the cupped surface.

The writer of the note, to which I have referred, attributes the cupping to the central portions of the nodules being composed of an older connective tissue, endowed with greater contractility than the circumference. This may be the case, but he makes no allusion to the condensed, almost solid, tissue of which I have spoken.

The sections under the microscope on the table were prepared as follows:—The young tuber was reduced in size with the knife, from circumference towards the axis, until sufficiently small to fit into the well of the freezing microtome. When frozen it was sliced in the direction I have mentioned, namely, at right angles to the axis, and finally the sections were stained and mounted in Farrant's solution. Each section shows a dense tissue in the centre, from which radiate bundles of fibres that form with connecting fibres a loose alveolar stroma. But few cells are seen, as they were washed out of the alveoli in the process of mounting.

ECCENTRIC, IRRITATIVE, OR REFLEX ALBUMINURIA.

By G. DE GORREQUER GRIFFITH, L.R.C.P. Lond., M.R.C.S., &c.,

Senior Physician to the Hospital for Women and Children; Consulting Physician-Accoucheur to St. Saviour's Maternity.

In your recent numbers I called attention to this form of albuminuria, hitherto, I believe, undescribed; and, certainly, if ever recognised, it has been so only by a few, for of many to whom I have named the affection I have not found any who had had cases of it in their own practice. Hence I am culling instances of it from others' experience when such can furnish it.

In a recent "Clinical" Dr. Robert Liveing says—"We often find skin affections influenced by disease of particular organs. For example, not long ago I had under my care in the Middlesex Hospital two severe cases of pityriasis rubra, of Hebra, associated with chronic albuminuria, and we remarked in both cases that when the condition of the skin improved for a time the albumen diminished, and *vice versa*. This occurred so many times that it would be impossible to regard it as an accidental coincidence . . . . . whether the temporary improvement in the action of the kidneys produced a change in the skin, or *vice versa*."

Viewing this chronic albuminuria as possibly the form I have described, I wrote to Dr. Liveing, who kindly furnished me with the following:—

"In reply to your letter respecting the two cases of pityriasis rubra with albuminuria to which I referred I feel quite sure that, in one of the two cases, the albuminuria was secondary to the affection of the skin. The albumen had entirely disappeared when I last saw the patient, and he had none of the symptoms of chronic kidney disease.

"In the other case the condition was different. There was serious organic disease of the kidneys, but as the skin disease had lasted for many years before I saw the patient, I cannot say whether it preceded or followed the albuminuria."

It is, I think, quite possidle that "the serious organic disease of the kidneys" was the result of "the skin disease (which) had laated for many years before Dr. Liveing had seen the patient." The *rationale* of this cause and effect I have very briefly explained in the January number of the *Practitioner* and the Medical Press and Circular.

(*a*) "A Clinical Treatise on Diseases of the Liver." By Dr. Fried, Theod. Frerichs. New Sydenham Soc., vol. ii., p. 288.

DISEASE OF HIP—EXCISION—RECOVERY. (*a*)

By JOHN K. BARTON, M.D. Dub., F.R.C.S.I.,

Surgeon to the Adelaide Hospital, Dublin.

James Parsons, 4½ years of age, was admitted into the Adelaide Hospital in May, 1877, suffering from well-marked symptoms of disease in the right hip-joint, in the first stage. There was severe starting at night, which was relieved at once by the application of the weight to the foot; there was no evidence of inflammation at the time of his admission, and I considered the case in the first stage. But about a month after his admission he had a rigor; his temperature and pulse rose, whilst his appetite (which had improved since the limb had been kept at rest) completely fell off. It was evident that suppuration was taking place, but no distinct abscess could be found for some days, when, a little behind the joint, towards the gluteal region, deep fluctuation was felt. A free incision gave exit to pus mingled with gas, and so marked was this that it not only bubbled through the pus, but fizzed out as if from an india-rubber bottle which was being squeezed. Immediate relief of the constitutional symptoms followed this incision; pus continued to flow freely, and a probe introduced through the opening entered the joint directly, when the head of the bone could be felt completely denuded of cartilage. The power of taking food was so far restored that milk and eggs were taken freely, but the smallest particle of meat produced diarrhœa. In this way the child continued through the summer; in September an abscess formed in the upper part of the thigh, and early in October another lower down; the diarrhœa became more and more easily provoked, and more difficult to restrain, while the discharge from the three openings was very profuse. I now decided on excision, which I performed on the 27th of October.

The child's state at the time of the operation was one of the most extreme emaciation. By means of a semi-lunar incision—which is, I think, the most convenient way—I very quickly found the remains of the head perfectly denuded of cartilage, rough, and worn away. The trochanter I found firmly adherent to its periosteum, and firm to the finger, and therefore determined to leave it. I removed the remains of the carious head with the bone forceps, and freely gouged the soft bone which formed the base of the trochanter and upper part of the shaft; the medullary cavity of the bone was freely laid open. The acetabulum felt smooth and granular; no dead bone could be felt; it therefore was left untouched. The wound was freely washed with sol. chlor. zinci, and dressings of lint, soaked in carbolic oil, were introduced into the wound. The little patient being placed in bed the resected limb was steadied by sandbags on each side, and by a 3lb. weight attached to the foot.

It is unnecessary to read the daily notes of his progress which have been kept. Suffice it to say that in carrying out the after-treatment the important principle of maintaining a free *drain for the discharge* was never lost sight of. The wound was well syringed out with a solution of chloride of zinc *twice* every day, and a piece of lint wetted in the same solution was as often introduced to the bottom of the cavity. This was steadily persevered in until the present date—nearly four months.

(*a*) A paper read before the Surgical Society of Ireland, Feb. 15, 1878. The discussion will be found at page 193.

His state to-day (Feb. 15, 1878) is as follows:—The child is still very thin and very pale, but decidedly fatter and better nourished than before the operation; his appetite is very good; he sleeps well; has no diarrhœa, but cannot eat meat without danger of bringing this on. The right leg is 1⅛ in. shorter than the left. It is straight, but the lumbar spine is still arched forward and the abdomen prominent; the operation wound is contracted to about an inch and a-quarter in length; in the centre of this there is an opening which leads into the cavity where the hip-joint was, and which is about two inches deep; fluid injected into this flows out partly through a small opening in the upper and outer sides of the limb: the lower of the two openings which existed before the operation has closed. The child has no pain, and can be lifted without any uneasiness when lying on his back in bed. He can move his foot, bend the knee of the resected limb, and bend the thigh on the pelvis to about 60°; this is partly due to movement of the pelvis, partly to movement in the acetabulum. When placed on his crutches and held by the nurse to steady him, he can walk, places the resected leg firmly under him, and appears to bear his weight on it, lifting and moving it forwards readily.

Mr. Barton handed to the President the head of the bone which had been removed, and remarked that this case was sufficient to encourage surgeons to adopt this operation in cases otherwise hopeless; that there was a good prospect of a useful limb, but little more than one inch shorter than the other, being preserved to the boy, whose life was, to all appearances, certain to be lost had the operation not been resorted to. But he had the pleasure this evening of exhibiting to the members of the Society a lad whose hip he had excised nearly five years ago, and whose case had been read before the Society some months after the operation. The boy was seventeen now, being thirteen at the time of the operation. The limb had been sawn below the trochanter, and it was consequently two and a-half inches shorter than the other, but with this exception the limb was in every respect as useful as the sound one. He asked leave to introduce this lad now, that the members might examine him before any discussion took place.

Clinical Records.

CENTRAL LONDON OPHTHALMIC HOSPITAL.

A Case of Glaucoma in which Sclerotomy was Successfully Performed.

By W. SPENCER WATSON.

The treatment of glaucoma by sclerotomy has now been tried in a considerable number of cases. In the majority, successful results have been obtained; in a few it has appeared as if the operation had been detrimental; in a minority the relief has been only temporary. The cases in which Mr. Watson has found sclerotomy preferable to iridectomy, are those of a subacute nature. He has, however, operated by this method successfully in a few more acute cases, in which the use of anæsthetics was contra-indicated. The rapidity with which it can be performed, and the consequently smaller amount of pain caused by it, as compared with that caused by iridectomy, render it more suitable for such cases. The result in the following case, though not brilliant, will bear comparison with many cases tested by iridectomy.

Mrs. ——, æt. 55 years, a nurse, had been under treatment for a fortnight, with an attack of what at first looked like iritis, there being only discoloration of the iris, and no severe pain, such as is characteristic of glaucoma. On January 13th, 1877, however, the eye affected —the left—became painful, and this was accompanied by pain in the circumference of the orbit and down the side of the nose. The tension of the eye was much increased (T3) and vision was reduced to the mere perception of light. The aqueous and vitreous humours were too turbid to allow of any view of the fundus oculi being obtained.

On January 13th, 1877, Mr. Watson performed sub-conjunctival sclerotomy upwards, and at the same time ordered the use of an opiate ointment to the brow and temple, and a draught containing bromide of potassium, at night.

Four days after the operation the tension was normal. There had been no pain. The pupil was perfectly round and normal. The vision was so much improved that the patient could count fingers.

Two months later vision had still further improved. No. 16 of Jäger's test types could be read. Tension remained normal.

Up to April of the present year the condition of the eye remained good.

L'HOPITAL COCHIN, PARIS.

Diffuse Aneurism of the Axillary Artery—Ligature of the Sub-clavian.

Under the care of M. Despres.

A woman, æt. 40, in consequence of the violence of her paramour, was admitted to the hospital in December last. She had had her right arm twisted behind her back, and in this position, had been suspended by her arms.

She felt suddenly a violent pain in the axilla, after which she lost consciousness. On the day after the event, M. Desprès observed, on the anterior wall of the axilla, a tumour manifestly fluctuating, with ecchymoses over the whole arm. Fourteen days afterwards, the patient felt during the night very acute pain at the top of the tumour, and the following morning it pulsated isochronously with the pulse, with a well marked *bruit de soufflé*.

Diagnosis.—Aneurism of one of the collateral branches of the axillary.

On the 12th January, a fluctuating tumour appeared at the posterior part of the shoulder, the blood without doubt penetrating the articulation. The anterior tumour was the size of an adult's head. Digital compression of the sub-clavian artery, as advised by Broca, was impossible. Some relief was afforded at first by the application to the tumour of flying blisters, but it steadily increased in size.

M. Desprès proposed disarticulation of the shoulder to the patient, who refused it decidedly. Ligature of the sub-clavian was then determined on, the operation taking place on Jan. 28th, in the presence of MM. Nicaise and Delens. M. Desprès employed the classic method:—Incision above the clavicle between the sterno-mastoid and the trapezius. Passing the clavicle he felt first for the sheath of the brachial plexus, and after raising the branches, one by one, reached the artery. The difficulty was to encircle it. After having seized it once, M Desprès passed a ligature below it, with a Deschamp's needle, and believed he had ligatured the artery. In the evening pulsation had disappeared in the tumour, this strange coincidence confirming M. Desprès in his opinion that the artery was secured. She survived the operation eleven days, dying of anæmia with humid gangrene of the arm—forty-three days after the accident.

The *autopsy* revealed that the ligature had embraced the most internal branch of the brachial plexus, and that the tumour developed from the axillary artery.

The Board of Governors of Cork-street Fever Hospital, Dublin, have recognised the valuable services of Dr. Grimshaw, during his physiciancy to the Institution by appointing him a Consultant. This is a very high compliment to Dr. Grimshaw's ability and industry, and all the more creditable to him because a similar distinction has never before been conferred upon any of the physicians.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At the last meeting of this Society, a paper was read by Dr. Broadbent on "A Case of Amnesia, with *Post-mortem* Examination."—The patient, an omnibus driver, æt. 49, of intemperate habits, had a fit, of which no accurate account could be given, in the beginning of October, 1877. From that time he was in the condition in which he was found on admission into St. Mary's Hospital on the 11th. There was no paralysis, excepting slight paresis of the right side of the face; but sensibility was defective over the right half of the body, limbs, and face. The speech consisted almost entirely of an inarticulate jargon, such expressions as "If you please," "Thank you," being only occasionally made out. It was difficult to know how far he understood what was said to him, although his replies appeared natural in tone and accent, and were accompanied by natural gestures and facial expression. He would also make long speeches to those around him, but he did not seem to know that his language was inarticulate. His want of comprehension of spoken words was shown by telling him to do something. On being told to give his hand, he put out his tongue; his actions were not appropriate, and he did not understand writing. He died suddenly, on Nov. 6th, and on *post-mortem* examination a considerable portion of the posterior half of the convex surface of the left hemisphere was found in a softened state. The greatest depth (three-quarters of an inch) and breadth of the morbid change was seen in a transverse vertical section made at the end of the fissure of Sylvius. Here the softening reached from near the superior longitudinal margin to within an inch of the inferior and internal edge of the hemisphere. The convolutions affected were proceeding from before backwards, the supra-marginal lobule and corresponding part of infra-marginal or first temporo-sphenoidal gyrus; more deeply and in a more advanced degree the postero-parietal lobule, the angular gyrus and the first and second temporo-sphenoidal convolutions in the same place; less extensively, the middle annectent gyrus and the part of the occipital lobe adjacent. The softening involved the tempero-sphenoidal lobe more completely than the parietal lobe membranes. Arteries of brain fairly healthy, of vertex opaque, and raised by fluid from convolutions. No other change observed. It was thought that the patient's loss of comprehension of words and his confusion of mind were due to the destruction of the channel from the auditory perceptive centre to the higher centre in which the name is associated with the idea which it symbolises, or to destruction of this same centre itself. At all events, there was in this case the association of a certain loss of intellectual faculties with a lesion of definite extent and seat. From this and similar cases in which the left hemisphere is affected, it would appear that the exclusive employment of this hemisphere, as the way out for language, involved its use as the "way in."—In reply to a question of the President, Dr. Broadbent said the patient was quite unable to express his ideas in writing, and he even held his pen in an aimless sort of way, not appearing to attempt the use of it. —Mr. Spencer Watson was very doubtful about the one-sided nature of the higher cerebral functions, and thought that the true explanation of cases of amnesia from lesion of one side of the brain might be found in a loss of balance between the two hemispheres, just as the function of walking is disordered if one leg be injured or lost.—Dr. Broadbent said the limitation of the function of speech to one cerebral hemisphere seemed abundantly proved by facts. No amount of lesion in the right hemisphere would produce loss of speech, whereas a very limited lesion in the third frontal convolution of the left side produced aphasia.

SURGICAL SOCIETY OF IRELAND.

The Sixth Meeting of the Session was held on Friday, February 15th, 1878, Dr. Minchin, and subsequently the President of the College, Dr. McDonnell, in the chair. The minutes of the previous meeting having been read by Mr. B. Wills Richardson, Hon. Sec., and confirmed,

AMPUTATION FOR UNUNITED FRACTURE OF FEMUR.

Mr. W. I. Wheeler said the specimen which he had the honour to bring under the notice of the Society had been removed from a patient who consulted him at his house with reference to the condition of his thigh, about three weeks since. When the patient entered his study he simply asked him (Mr. Wheeler) to remove his thigh. The history of the case was briefly this: In 1874, when travelling on one of the railway lines near Liverpool, a collision occurred, which resulted in a fracture of the patient's thigh-bone—a simple fracture about the junction of the middle with the lower third. The patient on that occasion remained lying out in the cold for about two hours before he was taken up, and it was snowing and freezing at the time. He was then put in the charge of a medical man in the neighbourhood of Liverpool, who gave the following account of his history, which had been printed, and which might now be found not uninteresting: "A gentlemen, of active habits, had his thigh broken by a railway collision, on the 25th of December, 1874. He sustained a few other superficial injuries, and was exposed for some hours in the frost and snow. The fracture, which occurred at the junction of the middle with the lower third of the femur, was simple and oblique in direction. He was put up in a long splint, afterwards placed in a M'Intyre splint, and finally in a plaster of Paris bandage. After seven or eight weeks the fractures still remained ununited, and after a consultation, it was decided that the ununited fracture was mainly to be attributed to a hacking throat cough caused by an elongated uvula, which constantly shook his frame and jerked the fragments. His bodily condition was soft from confinement to bed; so much so, that we considered it inadvisable to subject him to any operative procedure beyond snipping the elongated uvula, and painting his throat with perchloride of iron." On examining the patient he (Mr. Wheeler) found that the two fractures were distinctly separated from each other, and the inferior fragment ran up for about five inches above the superior fragment. There was no connection whatever between the fragments, as far as he could ascertain, and as proved to be the case at the time amputation was performed. The superior fragment was so very moveable that the patient, at his will, could bulge out the skin of the anterior portion of his thigh, which showed that there was no attempt at union. It was right to state that three or four operations had been performed on him, for the railway company, who were obliged to compensate the patient, sent down some London surgeons to deal with his case. He had been twiced pegged by Dieffenbach's method, once resected, and the limb put up in a starch bandage, the patient walking about with the starch bandage upon him; and finally—and this was from his own statement—he was beaten with a spoon over the region of the fracture for the purpose of exciting inflammatory action and a healthy condition. On inquiry as to his constitutional state, he found that he had suffered from specific disease, and also from scarlatina. He recommended him to give himself a chance of preserving his limb, and not to have it at once operated upon; but he declined to wait unless he (Mr. Wheeler) was able to promise him that his knee, which was ankylosed, would be brought into the bent position, and that he would have the power of using it, as his occupation would not allow him to have a stiff leg. As no such promise could be made to him, the patient was determined on having the operation performed. He (Mr. Wheeler) therefore amputated the thigh on Tuesday last; and the result was that he found that the inferior fragment had nothing whatever to do with the superior fragment, nor was it connected with it. There was a layer of muscles between the two portions of the fragments, and the inferior fragment was received into a cavity formed in the soft parts, and in that cavity there was a kind of adventitious membrane in which it appeared to work. A portion of the superior fragment was covered with fibro-cartilaginous tissue, and the inferior fragment was so moveable that it ran up even to the skin. On further examination he found another fracture had taken place lower down, which had united; and curiously enough, there was a regular aperture there which did not appear to close over. On examining the joint he found it was in a state of fibrous ankylosis, but there were no remains of rheumatic inflammation. The patient suffered from rheumatic gout, and although there were no osseous deposits, still it was characteristic of the gouty rheumatic affection there. He might mention that since the operation the patient had been

progressing tolerably well. He thought the specimen one worthy of being brought under the notice of the Society.

FATAL ANEURISM OF VERY SMALL SIZE.

Dr. Edw. L. Moss, R.N., said the specimen which he had to show the Society was one of fatal aneurism of unusually minute size. About ten days ago, the captain of the hold of Her Majesty's ship *Topaze* was engaged in getting up provisions, and when in the act of lifting a chest of tea weighing about 100 lbs., he fell backwards. He (Dr. Moss) was in the ward-room at the time, within instant call, and he was certain he saw the man within a minute and a half, and he was then quite dead. It struck him as a curious case, because up to that time the man had never been under observation or treatment in the ship; he had been 22 years in Her Majesty's Service, and his medical history-sheet as far as it went back, showed no indications of anything that would account for this sudden death. The man had not complained of illness to his wife, or to anyone on board. On making a *post-mortem* examination, he found a small aneurism springing from the first part of the aorta on the left side, half an inch behind, and to the right of the region of the left coronary artery. The whole of the aorta was in a diseased condition, and the opening of the aneurism occurred at the junction between the two posterior semi-lunar valves. The aneurism only measured the size of a pea, and the opening through which it burst a little more than a tenth of an inch in diameter. The region of the left coronary artery was dilated almost to the size of the mouth of the aneurism. The only interest that attached to the case was the small size of the aneurism, the fact of its having burst suddenly and ended fatally, without any previous indications of its presence. The heart was very fatty. The aorta was in a state of atheroma in several places. To preserve the heart, he had used what was, as far as he had seen, a new preservative, he alluded to thymol. Mr. Francis Darwin had recently pointed out that thymol was the most powerful known means of destroying bacteria, ten times more powerful than carbolic acid, and considerably more powerful than salicylic acid. It occurred to him (Dr. Moss) to use it on the present occasion. The heart had been ten days in thymol, and apparently no putrefactive change whatever had taken place, and the odour of the fluid was not unpleasant.

WHITE SWELLING OF KNEE.

Mr. Wheeler exhibited the limb of a girl who was admitted into the City of Dublin Hospital in October last. He saw her for the first time in June, and recommended her then to get under treatment, but circumstances over which she had no control prevented her from taking his advice at that time. The history of the case was this: about 8 years ago, when she was 14 years of age, after an attack of scarlatina, she got inflammation of the knee-joint. That got better under treatment, but for the second and third years she had more or less pain, until finally, the knee got into that condition known as white swelling. The cartilages were slightly ulcerated, there was granular degeneration, and the anterior crucial ligament was in a state of ulceration. He, therefore, determined to resect the joint. He made the incisions necessary for resection, and having sliced off a portion of the femur, which was healthy, he found a large abscess in the medullary cavity of the tibia. There was no thickening of the periosteum up the femur whatever. The external portion of the bone at the head of the tibia was healthy. He thought the case was interesting for this reason, that it was impossible to say it would not be a good case for resection; there was no reason to urge against that operation, for from external conditions the limb was one of the most favourable, and yet on examination there was that large abscess which would prevent the possibility of resection being probably successful.

UTERINE POLYPI.

Dr. Kidd showed a collection of tumours that he removed from the interior of the uterus on Wednesday last. Most writers spoke of polypi of the uterus being single. Dr West in his work on the diseases of women, said that sometimes two were found together, but never more than two; and Klob in his work on the Pathology of the Uterus, also described a case in which two polypi were found growing in the interior of a uterus. In the case he now brought before the Society, he found six. The patient was a young girl, about 25 years of age, completely blanched by hæmorrhage, and had been for some time under treatment in the Coombe Hospital, in the hope of checking the hæmorrhage. The ordinary means having failed to check it, he determined to explore the uterus, and he was quite aware before doing so, that there were tumours in it, but he could not tell the number. He now exhibited the six tumours he removed. The point of interest in the case was the fact of the number of tumours that were found which was rather exceptional. But there was another point of interest in connection with this case, and he thought a peculiarly interesting point. The patient was the sister of a girl that he had in the Coombe Hospital eleven years ago, and from whom he removed 29 uterine polypi (which he now also exhibited) at four different operations, and at intervals of four or five months. It was a rare circumstance to have such a number growing in the uterus, and he thought it a still more remarkable circumstance that they should have in those two sisters that tendency to the growth of a number of tumours. In the last named case, at the first operation he removed three tumours, they were all that could be discovered in the uterus. After some months, however, hæmorrhage returned, the uterus again grew in size, and on exploring it, he found nine tumours. Again it had to be explored after an interval of some months, and then 11 were found. After removing these, he sponged out the interior of the uterus with solution of the perchloride of iron, in the hope that it might alter the condition of the mucous membrane, so as to check the growth of these tumours. After a few months, however, he had again to explore the uterus, and then removed six tumours, making a total of 29. On the last occasion, he mopped out the interior of the uterus with a strong solution of nitric acid. He thought that was the first instance in which nitric acid was ever applied to the interior of the human uterus. The effect of it was that there was no return of the hæmorrhage, and the patient was now a shop assistant, and in good health, but he knew that her uterus was still large. The feature of a number of growths occurring in the two sisters, made him think it would be worth bringing it before the Society. He believed that this patient's sister was the first case in which tumours growing in the interior of the cavity of the uterus were ever removed. He thought it was the first instance upon record of their having been removed by surgical operation, as well as being the first in which nitric acid was applied to check the growth of such tumours.

Dr. B. Wills Richardson read a short paper on

THE CAUSE OF THE CUPPING OF FARRE'S TUBERA CIRCUMSCRIPTA OF THE LIVER,

which will be found on page 189.

Dr. Barton read a paper on

EXCISION OF THE HIP,

which will be found on page 190.

At the conclusion of his paper, Dr. Barton asked permission to have the youth, on whom he had successfully operated four years since, and who was now in attendance, examined by the members before the discussion on his paper was proceeded with. However, he was quite in the hands of the Society, and whatever the Society desired, he would submit to.

The President said it was contrary to the rules of the Society to allow a patient to be examined during their proceedings. It was usual for such examinations to be made after the business had concluded. At one time the request made by Dr. Barton would have been in order, but owing to some abuses, a rule had to be passed to prevent examinations of patients until the meeting had terminated. As, however, there was no further business before the Society, he would vacate the chair in order to conform to the Society's rule, and after the boy had been seen by the members, he (the President) would resume the chair, and then the discussion on Dr. Barton's paper could proceed.

The President then left the chair.

[The boy on whom Dr. Barton had operated, was then brought in and examined by the members.]

The President then resumed the chair, and observed that no doubt the operation was not a sufficiently common one to give surgeons very large experience of it,. but he believed some of the surgeons present had performed it.

Dr. Swan said he had listened with great interest to Dr. Barton's paper, inasmuch as he (Dr. Swan) was treating a case in which he performed the operation about three weeks ago. The case to which he alluded, presented most of the features which Dr. Barton had described. It was a case of operating, or of allowing the child to sink; diarrhœa was

present, and the formation of abscesses had occurred. With respect to the period of the disease at which the operation should be performed, was, he thought, a very fair subject for discussion, if the disease went on to rupture of the capsule and suppuration. They knew there were many cases of *morbus coxæ*, which seemed to stop in the first stage, at the stage of limitation of motion; but he thought there was nothing in the magnitude of the operation to prevent its being performed in the second stage of the disease, for the third stage was an inevitable consequence of the second. He thought they laboured under some disadvantage in the after treatment of such cases. At the same time in his, as in the case Dr. Barton had described, the recovery from the imminent symptoms was most marked on the removal of the diseased bone. He might state that on displaying the joint in his case, the cartilages appeared healthy, so that the disease did not commence certainly in the cartilages. The neck of the bone and the trochanter were diseased. He removed the head of the bone below the great trochanter. The acetabular cartilage was healthy; the ilium itself was to some extent diseased, and he removed a portion of it, but not so freely as he would, were he again to perform the operation. Since the operation, however, a portion of dead bone had come away through the opening, which, as Dr. Barton had done, he (Dr. Swan) had kept open as much as possible to allow a free discharge. The after treatment of the case had not been very difficult. He put up the child in the apparatus recommended by Mr. Sayre, which he (Dr. Swan) got made at Messrs. M'Adams and Corcoran's, Bachelor's Walk, a cuirass in which the child was very comfortable and by the use of which he was enabled to have him removed from one room to another, and thus give him change of air. There was no diarrhœa, his appetite had returned, his pulse became very strong, and the appearance of the patient's face had improved wonderfully. He (Dr. Swan) had every hope that the case would turn out a satisfactory one.

Dr. E. W. COLLINS said that Dr. Barton in his paper had laid down with some accuracy the reasons why the operation should be performed, and the period of the disease at which it should be done. He had stated distinctly in his paper that in his opinion it should be limited to the latest stage of the disease, and in that he (Dr. Collins) certainly quite concurred. He (the speaker) did not think it should be performed in the second stage of the disease, because he thought at that stage it was amenable to treatment. But when they came to the third stage—when abscesses formed and burst, when those abscesses were discharging, when pieces of bone were coming away, and when the health of the patient was beginning to yield, and when it became manifest that the patient would sink from constitutional disturbance, or else sink from long continued suppuration, and the supervention of visceral disease—then it was that that operation became absolutely necessary—not only, as Dr. Barton had stated, to save life, but even where life cannot be saved, to palliate and lengthen life. Exactly at this time last year he removed the head of the femur in a case of the kind where progressive caries had gone on; the abscess had burst below the trochanter as usual, and had been discharging for some months, and the health of the child had begun to give way—in fact, the child was so much emaciated at the time of the operation that, as in Dr. Barton's last case, it was believed by many that the child would not bear the shock of the operation. However, the child lived for eight months after the operation, but he regretted to say that after that period she sank of exhaustion. For many months the child went on admirably, and was able even to go about the ward with the help of a nurse and crutches. But owing to some circumstances that occurred about six months after the operation, the child was removed from hospital, and the care that she required was not given to her, and she sank of exhaustion, and died two months later. In that case he believed the operation, though it did not save life, certainly palliated it; and he thought that where the operation was demanded, even though it was not curative in its results, it was distinctly palliative; and the same was proved by Dr. Barton's own case, where he did not happen to be so successful as in the case of the boy whom he had just exhibited to the Society. In the case which he (Dr. Collins) had brought before the Society, he made a section of the bone below the trochanter as usual, and it appeared to him that Dr. Barton's last case even would show the advisability of making the section of the bone in that situation, and not through the neck of the bone, because Dr. Barton had stated that the disease had extended down below the point at which he made the section into the bone; and it appeared to him (Dr. Collins) that under those circumstances, as it was certainly the rule, it was well to go down as far as possible through the bone diseased. He had no experience of the apparatus—the wire cuirass—which Mr. Sayre recommended in the after treatment of these cases, and to which Dr. Swan had alluded. As in his (Dr. Collins) own case he simply employed the weight and pulley; and kept the femur apart from the acetabulum by a weight, as Dr. Barton had done, and steadied the limb by the application of sandbags, and that appeared to him to be the most simple and the most effective line of treatment. The cumbrous wire cuirass was effectual, no doubt, in cases where, as in America, the patient immediately after the operation had to be removed many miles. Dr. Sayre mentioned some cases where the patient, after an operation of the kind, was bound up in the wire cuirass like a mummy, and carried away for 50 miles. But in cases where that course was not required, it appeared to him that steadying the limb by sandbags, and employing a weight and pulley, answered all the requirements of the case. He might perhaps be allowed to allude to what was a very important matter in these cases—the condition of the acetabulum. The condition of the acetabulum in Dr. Barton's last case was remarkably favourable, it was covered by granulations. Now in the case which was under his (Dr. Collins) care, the acetabulum was extensively diseased; it was absolutely perforated, and he could pass his finger into the cavity which lay behind it. In his case also there was disease of the iliac fossa, which pointed to disease of the ilium; and he had no doubt that there was disease of the ilium. And yet under those unfavourable circumstances, where a portion of the acetabulum was gone, and the disease had extended up along the ilium, the child not only survived the operation, but survived it in comfort for a number of months.

Mr. W. I. WHEELER said he had listened with much interest to Dr. Barton's paper. There were one or two questions he would like to ask, and one of those questions was as to whether in the state in which Dr. Barton found the acetabulum, there was real lengthening of the bone? whether there was such real lengthening in that case of hip-joint disease, that the bone was shoved down by the granulations. That was denied by some, and stated by others, to be present as one of the stages which existed in hip-joint disease. He could not think it was desirable to operate in a case merely when it would prolong life. He thought that allowed the disease of the bone to extend down the femur, and allowed the acetabulum to become diseased, as well as other portions of the osseous system. He thought that when once suppuration had taken place, and the disease had not been stayed by measures which could be adopted even in the suppurating stage, he thought it was not advisable to wait and merely to perform the operation as a *dernier ressort*. With regard to the case mentioned by Mr. Collins, he (Mr. Wheeler) thought it illustrated the effects of leaving a case too long without operative interference. Mr. Collins had stated that in his case the child undoubtedly had disease of the acetabulum, and disease of the ilium. If that patient had been operated upon earlier, in all probability she might have recovered, and also there would not have been extensive disease set up. Furthermore when they had numerous cases of hip disease in which not only large portions of the femur were removed, but the acetabulum also, he thought in such cases where life had been prolonged, and a useful limb given, those portions of the diseased bone should be removed, and it would give a much greater chance for the patient's recovery. Were he to meet with a case of the kind—he had only met with one, in which he excised the head of the femur—he would wait until the suppurating stage came on, and then if the disease was not stayed, but progressing, he would operate, and not wait until it was merely for the purpose of saving the child's life.

Dr. WARREN said that having assisted Dr. Swan in the operation in the case to which he had referred, he merely rose to corroborate what Dr. Swan had stated as to that case, and to say that he thought the success of such cases depended upon whether the disease was confined to the femur, and that was the great point to decide, whether or not the disease was purely femoral. In Dr. Swan's case, from the position of the sinuses, they thought it was purely femoral. But there was extensive disease of the parts, and

they found that the ilium and the acetabulum were also diseased. As to operating early or late, he thought the joint was a far less important joint, when they considered the question of the synovial membrane than the knee-joint. He thought if they operated at all, it would be perhaps better to operate early. As to Mr. Collins's statement with reference to Mr. Sayre's apparatus being very complicated, he quite differed from him. He (Dr. Warren) thought it was one of the most simple apparatuses they could have. It was very light and useful, and easily applied. It had the great advantage of keeping the body perfectly fixed, as well as the limb. Certainly in Dr. Swan's case the apparatus acted most admirably.

The PRESIDENT thought Dr. Barton deserved their thanks for having exhibited the case which the members had seen that night. It was incomparably the best case of excision of the thigh bone that he had ever seen, and the result was extremely encouraging. They had not been much encouraged in their operations of that kind in Steevens's Hospital. Some time ago he removed the head of the thigh bone, and a short time before that his colleague, Mr. Colles, also removed the head of the thigh bone. He (the President) could not say that either of these cases, although they were not fatal from the operation, ran a course very materially different from what they would have done, if they had been left to Nature to perform the slow cure which they knew went on in many of those cases. He thought, however, that the patient exhibited that evening by Dr. Barton was an exceedingly encouraging case, and should make them desirous of giving a fuller trial to the operation. They must remember that there was a time when they were very unwilling to perform the operation of the excision of the knee, but in consequence of the very large number of cases of this kind that had turned out so successful, surgeons were greatly encouraged and were now much more willing to undertake the operation than before. Dr. Barton had rather repudiated the idea of having treated his case antiseptically, but he (the President) must say that he thought the case which had been dealt with so carefully as the one which had been detailed in which the syringing had been so carefully carried out, had been to a certain extent antiseptically treated. It was true it was not with carbolic acid, but the solution which was used went to a certain extent in the same direction, and also there was the free vent which was given; because they must remember that antiseptic treatment turned upon two things, first the prevention of the admission of septic matters; and secondly, to give very free vent, so that septic matter should not remain to be absorbed. That was the way of treatment of open wounds by the antiseptic method. He was rather surprised that the discussion had not taken a turn upon the advisability of performing the operation somewhat earlier in a totally different class of cases which they met with occasionally in which the disease set in very acutely, and instead of commencing slowly as in the case before the Society. They all knew that in those cases the symptoms set in acutely, nevertheless went on in the vast majority of cases to a fatal issue. In fact, in cases of that kind, the surgeon had to deal with one of the most formidable complaints to which flesh was heir. He did not know that he could tell them a single case of the kind that he had seen recover. He did not know whether Dr. Barton had any experience of this class of cases, but he (the President) thought that the case which Dr. Barton exhibited that evening was a most encouraging one.

Dr. BARTON, in reply, said that he had in his paper first remarked upon the very important question of the time of the performance of the operation. That had been referred to by one or two of the speakers, and he thought they were probably practically agreed as to that. Although they might differ a little as to the exact name of the stage at which they were to interfere, he thought they were all agreed that the grand point was that when the case had lasted so long that suppuration had taken place, it was evident the health of the patient was running down, and at the same time that they could remove the carious bone, be it ever so extensive, that then was the time for the operation. He did not agree with the observation that fell from Mr. Warren, that femoral disease was a necessary part, or that a successful case must needs be one where the disease was femoral. He (Dr. Barton) thought the grand point was to get rid of the carious bone. It was undoubtedly more favourable if the disease was femeral, but he thought that when they got rid of the carious bone was a more important point. There was another point that had not been referred to, and what occurred to his mind in connection with selecting the case went to strengthen what Mr. Wheeler had said, that the operation should not be postponed too long. They knew that amyloid degeneration of the liver and and kidneys proved fatal in those cases after some years. In the subject of the specimens on the table the boy lived four years. He went to school and went about, but the wound never entirely healed, and he died in the spring with disease of the kidneys, and on examination the kidneys were found to be extensively degenerated. Well, the surgeon had in those cases conscientiously to judge when the time had come, between, on the one side, the danger of operating too soon, when the ordinary mode of treatment might give a successful result without the operation; and on the other hand to wait until either the disease advanced extensively into the bones of the pelvis, or the degenerations had taken place in the viscera. That was always the stage at which it should be performed. The point he would refer to, and that was as to the length of time required for complete recovery. He thought that in those cases it was a very long time. The case he had detailed that night had been operated on four months since, and the case he exhibited that night, the wound was healed in about six months; but he could not say that that boy presented a complete cure for at least a year after the operation. With regard to Sayre's wire cuirass, he had not any experience of it, but Sayre's splint for the same disease he had repeatedly used, and he was disappointed in its action. In some cases it gave relief, but in the majority of cases he found it did not do so. Mr. Wheeler had asked whether there was lengthening in that case, and if the end of the acetabulum was filled with granulations. There was shrinking, and that shrinking was caused, he thought, by the head and neck of the bone being greatly absorbed. With regard to what the President had said about the antiseptic method of treatment, he fully concurred. He (Dr. Barton) did not mean to cast a slur upon the antiseptic method, but rather to point out in contra-distinction that in closing a wound by any method it appeared preferable to him to keep it open as much as possible. He quite concurred in the observations the President had made upon that subject.

The Society then adjourned.

MEDICAL SOCIETY OF DUBLIN.

FEBRUARY 6TH, 1878.

Dr. W. DOYLE read a paper on

A CASE OF OBSTRUCTED CIRCULATION

occurring thirty-four days after the birth of twins in a female, æt. 32, of nervous temperament, with an hereditary tendency to asthma, and who at the time of her illness was in a partially anæmic condition. The principal symptoms she suffered from were anasarca of face, legs, and feet, and the occurrence of three paroxysms of asphyxia which came on at nearly regular intervals with a corresponding diminution in their duration. I thought the asphyxial symptoms might be accounted for on the hypothesis of spasm of the capillaries or arterioles of the pulmonary artery; or they might depend upon thrombus of the right side of the heart, followed by the production of emboli of the pulmonary artery. The case made a complete recovery.

The PRESIDENT said the case was one of peculiar interest because the attention of the profession had been called to instances in which all the appearances of organic disease of the heart were presented—in which in fact disease of the heart was simulated—but in which it had been proved there was no organic disease of the heart at all. He had read with interest a paper in the last number of the *Edinburgh Journal* by Dr. Fotherg ll on this subject. It was a very interesting and nice point, because they were often led to hastily arrive at conclusions—for instance, with reference to fatty heart—and they found in the end that their conclusions were erroneous. In the paper he had referred to Dr. Fothergill alluded to emphysema of the lung as producing physical signs in the heart which had no positive origin in the organ itself. The subject was one of much interest.

Dr. M'SWINEY said that in the case which Dr. Doyle had brought before the Society he had presented them with a nut

which it was not very easy to crack. He had detailed the case with great minuteness, and he (Dr. M'Swiney) thought some of the characteristics rendered it extremely difficult to know to what category to refer the patient's illness. Dr. Doyle was under the impression that the affection was cardiac, and the effects of his treatment would tend to confirm that diagnosis; though there was no evidence of cardiac deterioration whatever in the heart when the patient was examined. In the absence of any further knowledge of the case he (Dr. M'Swiney) would be disposed to the opinion that it was a case of asthma occurring in a woman of highly organised sensitiveness of the nervous system, and although they had the assurance that the patient was of temperate habits, he should have diagnosed that she was addicted to alcoholic excesses.

Dr. Henry Kennedy said that when they considered that the mother of the patient was asthmatic they must look in some degree to that as having a most important bearing on the case, and in the next place they had pregnancy setting the system astray, and the patient not being well at the time of the occurrence of these attacks. Then they had the positive evidence afforded in hers not being a febrile state, and she had temperature which was below par, and they had urine which reached only 10·15, and with the occurrence of the paroxysm there was an extraordinary secretion of urine. Then they had the positive physical fact that the heart was larger than it should have been—a state not by any means uncommon, and comparatively easy of diagnosis—and he would suggest that that would cause an asthmatic tendency in a nervous female, and even extend to dilatation *pro tem* of the right side of the heart. He thought if they put these circumstances together and took into account the absence of inflammatory action, which he took to be certain, then he thought they had that form of disease. He would be curious to know the place where Dr. Doyle heard the pulmonary sounds. It appeared to him that there was a considerable deal to be learnt as to where they had to look for the pulmonary orifice. One of the latest writers on the subject (Dr. Balfour) put it at the junction of the second rib at the sternum at the left side, and put the aortic orifice at the junction of the second right costal cartilage with the sternum. He (Dr. Kennedy) must say that he thought they were lower than that, but he would be glad to hear the opinions of gentlemen engaged in hospital teaching on the point. If he mistook not there was more constipation probably in the case than might strike one at first. He need scarcely speak, in relation to any of those cases, of the immense importance of purgatives. He thought the case was very deserving indeed of consideration and discussion.

Dr. J. M. Finny thought the true explanation of the case was that a thrombus existed in the right auricle of the heart. The whole *rationale* of the case to his mind pointed to a thrombus in the right auricle. The reason he thought so was found in the condition of the woman. She was within a short time of pregnancy when the blood was in a state of hyperinosis, which tended to phlegmasia alba dolens, and thus involution of the uterus, which was going on after delivery of the twins, threw more work on the blood, which was not getting rid of effete matter by the usual safety-valve, lactation. Thus the blood was in a state of hyper-inosis, caused by the want of lactation and the anæmic condition of the woman. Having regard to the anæmic condition of the woman, probably the most favourable part of the case was that such a thrombus began in the right auricular appendix. He thought the treatment was all that could have been wished. The point he would like to clear up was as to the absence of the second sound. They knew there were two positions where that second sound might be produced. No matter how much the second sound of the aortic valves might be diminished on account of the small quantity of blood passing out of the ventricle as evident by the small pulse, there was no reason why the pulmonary sound should not be produced, unless the thrombus ran out into the pulmonary artery as well. It had been his custom to describe the pulmonary sound as being best heard below the second rib on the left side (he therefore must fall into the error committed in Dr. Kennedy's estimation by Dr. Balfour) and the aortic second sound as most distinctly heard below the second costo sternal on the right side. However, this was all a matter of intensity. He thought the Society must congratulate Dr. Doyle on the success of his treatment and the recovery of his patient after being in so serious a condition.

Dr. Doyle, in reply, thanked Dr. Finny for the very clear explanation he had given of the symptoms in the case before the Society. As regarded Dr. Kennedy's inquiry as to where the second sound of the pulmonary artery was heard he (Dr. Doyle) had heard it as described by Dr. Finny, as below the second rib to the left of the sternum. As to the want of the second sound he agreed with Dr. Finny that it was caused by the thrombus extending into the pulmonary artery, which pressed back the valves. There was no doubt, as Dr. Kennedy had remarked, that there was an asthmatic tendency in the patient, but there was one thing about it—it was not the ordinary form of asthma, nor constriction of the bronchial tubes. That was the first time the patient had ever suffered from asthma—the first time she had ever suffered from these paroxysms, and the strange thing about the case was that there was an interval between the second and third of ten days.

The Society then adjourned.

SUPERSTITIOUS MATERIA MEDICA.

We have frequently seen accounts of the strange things which entered into the materia medica of the ancients, and even the Chinese and Hindoos of the present day; but the *Nashville Journal of Med. and Surg.* publishes in its December number a paper by Meriwether Lewis, A.M., M.D., of Lenoir, Tenn., in which the writer vouches for the employment, even at the present day, of the following remarkable collection of nostrums by the people of his locality. Our New York contemporary, *New Remedies*, has collected some of the prescriptions, not merely for the amusement of the reader, nor to while away an idle hour, but in earnest, fully believing that the better the physician is acquainted with the peculiar views of the common people in regard to disease, and the more extensive his knowledge of their domestic remedies, the greater will be his influence over them for good. He will often find a secret course of domestic practice carried on contemporaneously with his own, and perhaps neutralising it completely. A distinguished Knoxville physician, while treating an injured hand, noticed at each visit a very offensive odour. Fully posted in regard to the popular *materia medica*, his suspicions were aroused, and, on examination, he found the hand was being poulticed with human fæces. We have no doubt in many parts of Great Britain the popular nostrums are equally absurd or disgusting.

Selecta e Prescriptis.

For Epilepsy.—"The skull-bone of a man."

For Love.—"It is pretty generally believed among the more ignorant classes that if the menstrual blood (*Sanguis menstruus*) of a woman be given to a man it will cause him to fall madly in love with the woman. The strong attachments of respectable men and disrespectable females is accounted for in popular opinions on this ground."

For Asthma.—1st. "Bore an auger-hole into a white oak tree at the height of the child; place in it a lock of hair, and drive in a pin. As soon as his height exceeds that of the position of the pin, he will be cured." The efficacy of this remedy depends upon the well-known fact that children outgrow a case of asthma. 2nd. "Eat a cooked rat. 3rd. Stand upon the paunch of a recently killed cow until it grows cold. 4th. Penis of a hog fried, and eaten without salt. 5th. Tobacco-leaves, or a plaster of snuff, applied to the naked chest."

For Thrush (*Aphthæ*).—1st. "Let a stud-horse blow his breath three times in the child's face. 2. Have some one who has never seen his father blow thrice in the face of the patient." (*a*)

To Prevent Thrush.—1st. "Soon after birth let the sun shine into the child's mouth." A certain prophylactic.

For Hives (*Urticaria*).—1st. "Egg-shell tea. 2nd. Sheep saffron. (*b*) 3rd. Tea of white hen-dung. 4th. Tea of ground ivy. 5th. Catnip tea."

(*a*) Hence bastards are much sought after.
(*b*) Common technical term for sheep-dung tea.

For Chills (Intermittent Fever).—1st. "Whisky and sumach berries (*Rhus glabrum*)." 2nd. "Yarn saturated with maid's water (*Urina Virginis*), and tied around the waist an hour before the expected return of the chill. First catch your maid. This is apt to produce some *local congestion* in youths, but such a phenomenon is neither pathological or serious. 3rd. A blister on each wrist and ankle."

To Increase Labour-pains.—1st. "Place the husband's hat on the head of the patient. 2nd. Infusion of black gum bark stripped down. If stripped up, it has the opposite effect. The bark of Prunus virginiana is believed to be emetic or cathartic, according to the direction in which it is stripped from the tree. It is also a popular idea that if a woman goes to sleep within an hour, or eats honey within a week after confinement, it will result in inevitable death."

For Difficult Dentition.—1st. "Tea of the inside of a chicken's gizzard." In this is plainly to be seen a marked anticipation of the modern digestive agent, "Ingluvin, from the *Ventriculus-Collaris Gallinaceus*." 2nd. "Rub the gums with the brains of a live rabbit." A remedy often employed with asserted benefit.

For Incontinence of Urine.—"Mole-skin tea."

For Burns.—1st. "Ointment of bamboo-leaves. 2nd. Certain persons who are gifted with such power can draw out the fire by blowing seven times upon the injured part." Such individuals are frequently in demand, as their curative powers are generally believed.

For Cramp.—1st. "Nine sow-bugs in emulsion. 2nd. Chamber-lye."

For Rupture (*Hernia*).—"Split a 'sapling,' pass the child through to the split, and tie up the split." As soon as it unites the child will be well.

For Toothache (*Odontalgia*).—"The blood of a snapping-bug dropped into the ear is an infallible cure."

For Dyspepsia.—1st. "Tea of muscadine vines. 2nd. Soot-tea."

For Scrofula.—1st. "Boil a flint rock (*impu resilex*) in water and drink the tea. 2nd. The blood of a black cock rubbed upon the enlarged glands."

For Irritable Temper in Children.—"Fodder-tea."

For Piles, Rheumatism, or Colic.—"Carry a buck-eye (*Æsculus glabra*) in the pocket."

For Stammering.—"Draw a hog's pancreas through the mouth."

For Weed (*Puerperal Mastitis*).—1st. "Tie a bag of sulphur around the neck. 2nd. Poultice of cow's dung to the breasts."

For Ringworm.—1st. Rub with green walnuts. 2nd. Ointment of soft soap and gunpowder."

For Colic.—1st. "Cockle-bur tea (*Xanthium*). 2nd. Boil an old pipe and give the tea."

For Shingles (*Herpes Zoster*).—"Cut off a black cat's tail and apply the blood to the eruption." Vouched for by a minister who has used it successfully. (!)

For Hæmorrhage of the Lungs.—"Rag-weed tea."

For Wens or Lupus.—"Rub a dead man's hand over the tumours."

On leaving England, the Crown Prince of Austria sent a donation of £20 to the *Dreadnought* Seamen's Hospital, Greenwich, "in recognition of the humanitarian and cosmopolitan aims of the institution and the energetic endeavours of the committee to achieve the noble purposes in view."

The Blackheath Dramatic Club gave an entertainment on Monday, Tuesday, and Wednesday last week, in the New Cross Public Hall, in aid of the Kent Dispensary and the *Dreadnought* Hospital; each evening, the spacious hall was crowded, and about £150 is expected to accrue to these charities in consequence.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 6, 1878.

THE ARMY MEDICAL REPORT FOR THE YEAR 1876.

The Army Medical Report for the year 1876 is, on the whole, very satisfactory; and we propose to devote a few remarks to the health of the troops serving in the United Kingdom. Out of 87,758 non-commissioned officers and men, the admissions into hospital was in the rate of 813·7 per 1,000 of the strength; the average number of men in hospital daily was 3,475, being at the rate of 39·60 per 1,000; and the death-rate was 8·43 per 1,000 men. Compared with the corresponding rates of the preceding year, there is a decrease of 17·6 per 1,000 men for admission, of ·93 per 1,000 for deaths, and of ·87 per 1,000 for daily sick. Of the 71,405 cases admitted into hospital, more than 14,000 are classed under "general diseases," 3,787 under the *febrile* group, and 11,955 under the *constitutional* group. The febrile diseases include the fevers, influenza, erysipelas, &c., cases of continued fever alone amounting to 1,808. The constitutional diseases include rheumatism, syphilis, scrofula, phthisis, scurvy, anæmia, &c.; and of the 11,955 cases above-mentioned, we have 6,444 due to syphilis, 4,126 to rheumatism, and 1,130 to phthisis. The chief diseases that figure among the "Local Diseases," are those of the respiratory system (7,910), digestive organs (9,979), urinary organs (6,966), and disease of the cutaneous system (9,503). Nearly all "injuries" are of an accidental nature, no fewer than 10,482 cases arising from accidental causes. These facts we mention as showing the chief diseases from which our home troops suffer. The rate of prevalence of most of the diseases above-mentioned was lower than that for the preceding year. The eruptive fevers, however, were more prevalent, owing to the outbreak of small-pox, and even of this fever

the admissions were only 25. With regard to syphilis, the rate of admission for all districts is ·9 per 1,000 lower than in the preceding year. For the primary form of the disease, the rate of admission was 46·0 per 1,000, for the constitutional form 27·4 per 1,000. It is also a significant fact that the ratio per 1,000 admitted for primary venereal sores into fourteen stations under the Act was only 33, while in the fourteen stations *not* under the Act, the ratio was 82; and for gonorrhœa, while the ratio was but 68 in the protected districts, in was 89 in the unprotected districts.

The army affords a good field of observation with respect to vaccination, and therefore it is worth remarking that out of 22,302 recruits found fit for service, there were only 727 who had neither marks of vaccination nor small-pox, and that there was a slight increase in the ratio of recruits with marks of vaccination. Again, there were 10,358 soldiers vaccinated during the year with *fresh lymph*, and 17,269 with *preserved lymph*. Of the former there was a perfect vaccine vesicle in 4,717, a modified one in 4,400, a failure only in 1,241; whereas in the latter class the corresponding numbers are 5,346, 6,432, and 5,491. Thus, while the ratio per 1,000 of failures was only 119·8 when fresh lymph was used, it was 318·0 in the case of preserved lymph.

The sanitary condition of the various districts or stations is also mostly satisfactory. That of Aldershot is good, and several sanitary improvements are in course of construction. The same may be said of the Eastern District, where the barracks, hospitals, &c., are "all that could be desired." As usual, venereal disease has mostly contributed to the general amount of sickness; but "it is satisfactory to be again able to report most favourably upon the salutary effect of the Contagious Disaases Acts at Colchester, the only station in the district where it is in operation." Surgeon-General Watt gives similar testimony with regard to the South Eastern District. "I must," he says, "reiterate my opinion that these enactments exercise a salutary influence on the health of the soldier, a view in which I am supported by nearly all the medical officers in command." In some of the protected places, however, such as at Chatham and Woolwich, venereal diseases have largely prevailed, owing to many of the men having come from unprotected places, and to some going away for a short leave to London and elsewhere. Thus at the latter district we are told that the admissions for venereal disease continued to cause a great deal of inefficiency, being equal to about one-sixth of the entire admissions. At Woolwich, however, great difficulties exist against the better prevention of this evil. Not until all the stations are under the influence of the Contagious Diseases Act, can we expect the beneficial effects of the Act in the protected districts to be so marked as they should be. In other respects the general health of the troops, both at Chatham and Woolwich, has been fairly good during the past year. But with regard to Woolwich, Surgeon-General Small draws attention to the fact that the largest mortality has occurred from diseases of the respiratory system, and, more especially, to the predisposition there is to contract chest affections amongst those soldiers who return to Woolwich after long service in India, and whose constitutions are more or less impaired by the climatic diseases of that country. We certainly agree with Surgeon Small that it would be more beneficial to the State, and to the soldier, were such men on first arrival in England quartered elsewhere. Intermittent fever was also very prevalent among those troops who had either recently returned from India, or who had had considerable previous Indian service. Surgeon-General Bowen gives a good report of the Southern District, and especially of the working of the Contagious Diseases Act at Parkhurst and Portland. He considers it would be a great advantage if the Act was brought into operation at Portland, Weymouth, Cowes, and Newport. The same remark is made by Surgeon-General Holloway, with respect to the Dublin Garrison, where venereal disease has been very prevalent.

In looking over these reports, we are struck with the activity that is evinced in the sanitary improvement of the various stations. Thus, in the Chatham district, various sanitary services have been executed by the Royal Engineers during the past year; the drainage, water-supply, &c., have been improved, and a number of works were proposed for execution in 1877. The same may be said of almost every other district, as there is none in which important sanitary improvements have not either been effected, recommended, or in course of progress.

Considering the importance we have always attached to the improvement of the *physique* of the troops by means of regular and systematic exercise, we are glad to find that there are few stations in which gymnasia have not been established, and that very satisfactory reports are given of the salutary effect they have had upon the health of the men. In the Brompton Barracks, there is a gymnasium in which the troops undergo a regular course of training, and the medical officers bear testimony to the good effects of this course on the men's health and *physique* generally. At Aldershot, the gymnasium is attended compulsorily by young officers and soldiers, and is also well attended voluntarily. Medical officers speak of it favourably, and of the beneficial results to recruits.

THE MEDICAL PROFESSION AND TOTAL ABSTINENCE.

No one, who is conversant with the periodical literature of the day, can have failed to notice the large amount of discussion that is everywhere devoted to the merits of the total abstinence movement. An almost unprecedented reformation in the habits of the people is now being urged upon all classes of society; and as the medical profession can have a very powerful influence in promoting or checking this reformation, it is our duty to consider what action we should take with regard to it, and what advice we should give to our patients who consult us as to the propriety, or not, of their being guided by its teachings.

In a course of lectures, which Dr. Richardson is now delivering on "Practical Abstinence, and the difficulties that lie in the way of its attainment," the first of which is published at length in the pages of *The Temperance Record*, the lecturer draws particular attention to what he calls the medical difficulty, and which relates to the

initiative action of the profession in favour of total abstinence. It is said that the difficulties in the way of this great temperance movement are increased by the apathy of the medical profession, and that if medical men would generally support it, the cause would find ready entrance into every house, and "would progress with a rapidity which knows no parallel." There can be no doubt, that such would be the case, for considering the opportunities that medical men have of ventilating their opinions among the community, and the influence which their opinions have in respect of everything that concerns their patients' health, a very rapid and wholesale revolution would take place in the drinking propensities of the public, were the whole profession convinced that man could do as well, or better, without than with alcoholic liquors. But the fact is, a large majority of the profession entertain the very opposite opinion, and this circumstance, more than any other, prevents them from siding with the total abstainers. Others again, have thought little about the matter, have no decided opinion either one way or the other, and in their practice are guided more by the feelings and the taste of their patients, than by their own convictions on the subject. There is still a third party in the profession, which, whatever their views on this great question may be, have not, as it is often said, the courage of their opinions. They see everywhere so much prejudice in favour of old practices, and so many people who are impelled by the force of habit and example, to keep to the old groove, that they have not the moral courage to say what they think, particularly as by so doing, they run the risk of falling out of public esteem, and of losing the confidence and patronage of their patients. Now, it may be justly said, that all these parties are more or less in the wrong. For those medical men, whose views on the subject are entirely opposed to the doctrine of total abstainers, are, in many cases, themselves almost as much under the influence of prejudice and preconceived opinion as the public are; inasmuch as their convictions have not been based upon ample experience and careful observation. But if dogmatism is to be deprecated in questions of this kind, doubt that is capable of being removed, is almost equally culpable; and, therefore, those members of the profession who are in doubt as to which side to take, are, in the interests of their patients, in duty bound to do all they can by patient observation and experiment, to arrive at the truth, and not to allow their conduct to be influenced solely by popular prejudice, and caprice. Still more blameworthy is that section of the profession, which, although they may have strong opinions in favour of total abstinence, have not the courage to express them, or to carry them into practice, but would rather wait until public opinion had become so far changed, as to admit of their carrying out their views without fear of opposition. Dr. Richardson thinks that the medical profession should not be expected to lead, but should be led by, public opinion. "The medical mind," he says, "must be in accord with the mind and current will of the majority of the nation. . . . The verdict of the majority of the people would bind, therefore, the profession of medicine, even if the mind of the profession were as universally convinced of the whole truth of abstinence as the minds of some of its members are. In this regard," he adds, by way of illustration, "the professional mind is in precisely the same position as the mind of the statesman, with the important difference that it is infinitely less powerful and far less independent, having to live by its work, and to be paid as well as a public servant." This observation, however, appears to us faulty both in argument and in illustration. On subjects on which the public are as capable of forming an opinion as are members of the profession, it would be quite right for the opinion of the latter to be bound by the verdict of the majority of the nation. But the case is very different when the solution of the question involves a certain amount of scientific knowledge and a special kind of observation and experience. It is quite true that the mind of the executive statesman must be in accord with the mind and current will of the public, because in this case the propriety or not of any reforms that may be contemplated is a question on which they are themselves in as good and sometimes better position to form an opinion than the statesman. In such a case the collective opinion of the public must necessarily carry great weight, and is in most instances irresistible. But when the question turns upon the action and uses of alcoholic beverages both in health and disease, and upon the virtue or impropriety of total abstinence, we have to deal with facts with which the public cannot be expected to be so conversant as the medical profession. To say, then, that the mind of the latter, even if universally convinced of the truth of total abstinence, should be bound by public opinion on the subject, is to say that medical men must entirely forego their prerogative as scientific men, should wait for that tide in the opinion of the public which they themselves, in virtue of their scientific attainments and special experience, should take an active share in turning. That we are not wrong in adopting this line of argument is shown by the fact that there is scarcely a medical man whose opinion of the total abstinence movement is not received by the public with the greatest deference and respect. He is looked upon as one on whose advice the utmost confidence can be placed, both in virtue of his scientific knowledge and of his professional experience.

TRAINED NURSES FOR THE SICK POOR.

On Wednesday week, a meeting was held at Grosvenor House, under the presidency of the Duke of Westminster, to assist an Association which has come into existence for the praiseworthy object of training nurses for the sick poor. A number of noblemen and gentlemen rallied round his Grace the Duke of Westminster, on the occasion, with a view of establishing a fund wherewith to carry out the work of a "National Nursing Society." In addition to the work of providing nurses to attend upon the sick poor at their own homes, the Society wish to establish a training-school for nurses, in connection with one of the London Hospitals, and for the purpose of raising the standard of the class of persons usually employed as nurses. The Society is already in operation, and with a small staff at command, it has already succeeded in doing a considerable amount of good work. One of the objects of this Association is to remedy pre-

sent evils, and supply the poor with nurses especially trained for the work; for the life of the patient will often rest upon the care and desire the attendant may manifest in the discharge of her duty, as well as upon an implicit obedience to the directions of the medical attendant. But we can scarcely be expected to agree with Miss Nighthingale, that to our nurses we may look "to raise the homes of the poor, so that they might never fall back again into dirt and disorder; to pull through life and death cases without any sick-room appurtenances, to keep whole families out of pauperism by preventing the home from being broken up, drag the noble art of nursing out of the sink of relief doles; and practically, carry out the principles of preventing disease, by stopping its causes." If all this can be done by good nursing, then doctors may expect to be very soon superseded. Enthusiasts of the Miss Nightingale's type seem to forget how much of the improved nursing of the day is owing to the efforts and self sacrifice of the medical profession. How great has been the difficulty in enforcing the simplest rules of the sick-room upon all classes, very often, no doubt, from the want of a better educated class of nurses, as well as the difficulty of finding a working head, who would personally keep the training and nursing at the highest pitch, without manifesting a desire to go beyond her sphere of duty! Nevertheless, we go with those in this matter who believe that skilled nursing is an important element in the cure of the patient, and that the kindly-hearted ministration of a trained nurse is a great gain in every way upon the Sarah Gamps of our earlier days; but most common-sense people are as well aware as we are, that "the bread winner" cannot be brought back to health, solely by the good nursing about to be inaugurated by the "National Nursing Association."

It would be well, too, if "the noble art of nursing" could be "dragged out of the sink of relief doles;" but the education of nurses costs money, and to provide a staff, the Society says it requires a capital of £20,000, and a guaranteed income of £5,000 a year. This large amount is required for the purpose of training and educating probationers. We are inclined, however, to think that the institution, in so far as may be practical, should be self-supporting, both with regard to education and to the nursing of the sick poor, if for no other purpose than that of encouraging habits of thrift and forethought amongst all classes of the community, and by way of inducing the working class to provide against the incidence of sickness. It is quite possible, too, even in the case of a nursing institution, that an undue proportion of the funds may be spent upon administration, "erecting, purchasing, and renting district homes." And it is a further question, a most important one, whether the help given, is given for whom it is really intended, or goes to those for whom it would be better on the whole not to have it.

A TELEGRAM has reached the Foreign Office from Constantinople to the effect that Dr. Attwood, of the Stafford House medical staff, who had been for some time missing, was safe and well treated at Otterkine.

A DISSECTION OF STUDENTS' DEMONSTRATIONS.

STUDENTIAL effervescence is a phenomenon, the observation of which has engaged the attention of medical teachers for all time, and for which no remedy is ever likely to be found, as long as the medical College continues to be a sort of "fourth form" of the boy's school, to which young persons who are still children in years and mind, are moved forward fresh from the schoolroom and the birch. "Children will be children," and if the circumstances of the medical profession are such as to make eligible for its ranks children of 14, with the smattering of education obtainable in the dame's school, and with the romping of the playground fresh upon them, we must rest content with frequent demonstrations of childish frivolity and schoolboy carelessness. "Larks" are indeed a nuisance in either lecture-room or hospital, but time has consecrated these places to their evolution, and teachers must be content; it is a different matter when these foolish ebullitions take place in public places, and are elevated to the rank of demonstrations of opinion; and when they assume this condition it is time to remonstrate against them. If encouraged or permitted these proceedings may become a nuisance to the community at large, and the law may have to be invoked to put a stop to them—a result which would create illwill, and be discreditable to the profession.

We have read last week of the appearance in a police court of some half-dozen unwisely zealous young gentlemen, who created a riot upon the premises in which a bevy of simpletons had assembled to repeat to each other the threadbare falsehoods with which anti-vivisectionists excite themselves. These would-be humanitarian old persons might have been allowed to exchange what, no doubt, they would call their ideas with each other, and to preach their exaggerations and untruths into the ears of a few insignificant and uneducated persons in their own parish, and no one would have either cared for what they said, or would even have known of their existence but that a knot of medical students in search of amusement chose to bring them into notice, and give them a grievance by creating a riot in their meeting-room. No doubt these young gentlemen were annoyed at the persistent promulgation by these persons of calamnies against the profession to which they were themselves to belong, and they thought a "lark" in this direction would be as amusing as in any other, and therefore involved themselves in an unseemly row, for which the magistrates condemned them to pay £10.

We confess we cannot pity them in the infliction. No person of sense, we presume, could have advised them to disturb the meeting in question, and in acting upon their own impulse to do so, they materially injured the position, and lowered the dignity of the profession whose champions they constituted themselves. Medical men and practical physiologists do not wish to be looked down upon by the public as caring anything for the ridiculous maunderings of anti-vivisectionists. They have perfect confidence that all thinking people will recognise their relation to the practice of vivisection—the objects with which they engage in it—and the feelings of humanity with which they endeavour to perform an irksome scientific duty, and they are ready to let all the *un*thinking people (numerically

strong, but intellectually insignificant) nurse their own delusions. It is a disaster when meddlesome students alter this attitude of the profession, and give to fanatics a grievance to substitute for the argument which they lack.

After all, however, this outbreak of studential spirits had reference to a professional matter, and we cannot be hard on the mistaken impulses of young men whose professional character is assailed. But their effervescences become really annoying, when they take the form of political processions, and of stump declamation upon subjects respecting which they can know nothing. If the procession of medical students to Westminster Hall had been sufficiently noisy to attract attention outside London, it might have produced serious political results by making ridiculous in the eyes of European diplomatists the Government in whom these young gentlemen were good enough to express confidence. A vote of sympathy with the policy of the Government of the United Kingdom, emanating from a harum-scarum crowd of jolly semi-schoolboys, is sufficiently farcical to excite the risibility of the imperturbable Gortschakoff, or the ascetic Von Moltke, and we can thoroughly appreciate the discomfort which the Minister must have felt in finding himself obliged to treat such a representation of opinion as serious and important.

We very much regret to observe that the advisers of the students themselves are unconscious of how ridiculous their "demonstration" made them. The *Students' Journal* says:—"The most noteworthy event of the last fortnight in the student world has been the great political demonstration by the students of the Metropolitan hospitals, which took place on the 7th inst. Such manifestations, if properly conducted, will do good just now in stirring up a patriotic feeling among the people generally, for patriotism is more contagious than even the plague. I am pleased to hear that there is some talk of another demonstration next week, and I trust every student will feel it his duty to be present, so as to make it as imposing as possible. If the meeting takes place, I would suggest that, before proceeding to the Houses of Parliament, a vote of sympathy with the Turkish nation should be passed, and that the whole of those present should march in procession to the residence of the Turkish ambassador, and present him with copies of the resolutions passed at the meeting. He would, I am sure, be vastly pleased by such a manifestation, and would not fail to acknowledge the compliment."

We certainly look to the teachers who have influence over the metropolitan students to discourage with emphatic firmness the tendency to involve themselves in political "larks." As a rule, these young gentleman are not of an age to give great weight to their political views, and we venture to submit that they might advantageously waive their own prerogative of settling the Eastern question in favour of the Ministry, and to Members of the Houses of Parliament, who, though, probably, not as well informed on the subject or as cool of judgment as the medical students, have obviously more leisure to devote to the subject than these young gentleman can be supposed to enjoy.

THE deaths from small-pox were considerably less last week in London, being only 39 as compared with 55 and 47 of the two previous weeks.

Notes on Current Topics.

Infantile Paralysis.

UNDER the term "infantile paralysis," two very different classes of cases are included. In the one class the muscles are rigid, and in the other they are flaccid; and these two classes of cases present many differences in their clinical history, pathology, and results of treatment. Towards the end of a long and interesting article on this subject in the current number of the *Obstetrical Journal*, Mr. William Adams sums up the chief points of difference and of agreement between these two classes. 1. With regard to the *period and mode of seizure*, cases of infantile paralysis, with flaccid muscles, never occur at, or immediately after, birth, the time when the worst cases of paralysis with rigid muscles occur. But both classes of cases generally occur from six to eighteen months during the first dentition; and the flaccid class are sometimes ushered in by a febrile attack, simulating acute rheumatism, a circumstance which, according to the experience of Mr. Adams, never happens in the rigid case. 2. In the flaccid class of cases the *mental faculties* are never affected; whilst in the other class they are often seriously impaired. 3. *Fewer muscles* are involved in the flaccid than in the rigid class; for in the latter all the muscles in the limb or limbs may be involved. 4. In the flaccid class the *temperature* of the paralysed limbs is always much lowered, so that sometimes the normal temperature cannot be restored and maintained by any means. In the rigid class the temperature is very little affected. 5. In the former there is always a tendency to *spontaneous recovery*, perfect in slight cases, and to a considerable extent in the more severe; but in the latter or rigid class of cases, no tendency to improvement ever occurs. 6. In severe cases of the flaccid class there is a tendency to *fatty degeneration* in the paralysed muscles; whilst no such tendency exists in the other class of cases. 7. When any contractions or deformities have occurred in the flaccid class, *tenotomy* may be dispensed with, mechanical extension being alone sufficient. But in the rigid class, tenotomy offers the only prospect of improvement. Contractions, however, may often be prevented in both classes, by shampooing, and the daily use of passive exercises. 8. With regard to *reunion of tendons after division*, this feeble union arises from defective reparative power in the flaccid, but from too wide separation of the divided tendon in the rigid, class of cases. 9. *Galvanism*, especially the mild continuous current, is of the utmost value in the flaccid class, but of no use whatever in the other class. 10. With respect to the *relative frequency of these two classes*, it is difficult to form an opinion, but Mr. Adams believes the cases of flaccid muscles to be much more numerous than the rigid class. In the former, a transient paralysis may lay the foundation of persistent deformity, and thus the flaccidity of the muscles having disappeared, may escape observation.

Medical Students and the Anti-Vivisectionists.

"BECAUSE the public chose to protest against the introduction into this country of the vile, degrading, and barbarous practice of vivisection, these sucking doctors

who know that no arguments can overcome the agitation, betake themselves to physical force. I think the magistrates who excuse their conduct, as Mr. Chance appeared to a certain extent to do, have a strange idea of their duty. The students should have been sentenced to a week's imprisonment, at least. The knowledge that the medical men of the future are thus conducting themselves is a melancholy one indeed. If the magistrates did their duty in the matter, they would confine these young barbarians in a prison cell. This might teach them manners, although, unfortunately, it could not give them any experience of the horrible tortures that they are in the habit of inflicting on inoffensive animals, many of which are infinitely their superiors in natural nobility."

Such is the flippant and scurrilous language which the *Echo* thinks proper to admit into its columns. We should be the last to excuse the conduct of certain medical students on the occasion to which the writer refers; and we feel certain that such conduct has been as strongly condemned by every member of the medical profession, as by the opponents of vivisection themselves. But they did nothing to justify the wild and abusive language that has been used by more than one newspaper correspondent. All over the world students of all denominations have often had rough and ready ways of giving expression to their opinions; but in this respect they are not one whit worse than other students, as, for instance, the undergraduates of Oxford and Cambridge, whose fracas have often attracted the attention of peace-loving citizens.

In some respects we cannot be surprised at the indignation which the conduct of the students excited among the anti-vivisectionists, for these students had dared to oppose a crusade which was characterised by a remarkable amount of fanaticism and prejudice, but which nevertheless, in the eyes of the anti-vivisectionists, appeared to be a just and holy cause. Unfortunately, they weaken their case by the gross misrepresentations and uwarrantable accusations they bring into the discussion of the subject, and therefore we cannot be surprised that they libel a whole class for the faults of a few.

Chloroform and Ether at Netley.

In a short report on this subject, by Surgeon-Major Porter, it appears that during the year 1876, chloroform and ether were administered at Netley Hospital in 21 and 13 cases respectively. The average time taken to place the patient under the influence of chloroform was 8 min. 5 sec.; the shortest time being 2 min., and the longest 20 min. The average time patients were under the influence of it was 11 min. 20 sec. The smallest quantity used was 1 drachm, and the largest, 12 drachms, the average being a little over 3 drachms. In two cases there were most alarming symptoms, sudden failure of the pulse, lividity of the countenance, and feeble respiration, obliging the operator to discontinue the anæsthetic, and restore suspended animation, by pulling the tongue forward, using artificial respiration, and allowing a free current of air to pass over the body. With regard to ether, the average time taken to place the patient under its influence was 18 min., the shortest being 7 min., and the longest 45 min. The smallest quantity used was 2½ ounces, and the largest, 14 ounces, the average being 6½. The chloroform was administered by means of a handkerchief or towel folded into the form of a cone, or sprinkled on thin flannel stretched on a wire frame. The ether was given with Dr. Thomas Skinner's apparatus, "Punch's Nose," as described in the *British Medical Journal* of October 2, 1875.

The Lectures at the Irish College of Physicians.

The fourth lecture of this year's course of scientific lectures in the King and Queen's College of Physicans was delivered on Monday, February 25th, by Dr. Purser. The principal facts which are known as to the functions of the different tracts of white fibre in the cord were stated. The difficulties and uncertainties which beset experimental investigation were pointed out. The results of the more important researches were detailed, particular notice being given to those recently carried on in Leipzig, as being better conceived and more perfectly executed than the experiments of earlier physiologists. The hyperæsthesia which follows limited lesion of the cord was stated to be probably due to destruction of inhibitory fibres. The knowledge to be derived from the facts of human pathology was then considered. It was shown that as yet even the best defined diseases, such as posterior or lateral fasciculated sclerosis, are able to throw very little light on the functions of the different parts of the medullary cortex. In conclusion an attempt was made from a consideration of all circumstances to trace the course of sensitive and motor impressions through the cord. It was shown that while we possessed a fair amount of knowledge as to the paths of motor impulses, many facts existed which made sensitive conduction still quite inexplicable.

Sir John Lubbock's Dental Bill.

This unhappy attempt at legislation, to which we have referred in our two last issues, in a danger of attack on the opposite side of our onslaught. The *Chemist and Druggist* sounds the trumpet against it because it may possibly "stamp out dental druggists."

"This Bill," it says, "seems to seriously threaten the existing rights of those many chemists and druggists who, without making any false representations whatever, have joined a little dentistry to their drug business. Some of them have acquired considerable skill in the extraction of teeth, and it would be a needless attack on them and on the public convenience if this right were withdrawn. The Bill, as we read it, would not prohibit the actual performance of any dental operation by an unregistered person, but it would prevent the assumption of any such title as that of "dentist," and possibly, too, the exhibition of any such announcement as "teeth carefully extracted," &c. Of course, too, an unregistered person would not be able to sue for any claim in respect of dental services.

"We sympathise with the objects of the Bill to some degree; but if its promoters really intend to stamp out dental druggists altogether, we think, on behalf of the latter, and also for the benefit of the public, and especially of poor persons, the Chemist' Trade Association should offer a serious opposition to it."

The Ex-Officio Governors of Irish Lunatic Asylums.

Mr. O'Shaughnessy has given notice that on Friday next he will move for copies of the order of the Privy Council of Ireland of the 17th day of February, 1822, appointing the Mayor of Limerick and other persons governors of the Limerick Lunatic Asylum, and the

order of the Privy Council of the 26th day of January, 1876, rescinding or varying the same; of any correspondence on the subject in the year 1875 between the resident surgeon of the Limerick Asylum and the Inspector-General of Lunatic Asylums in Ireland; and any correspondence between the present Mayor of Limerick and the Chief Secretary to the Lord Lieutenant relating to the right of the mayor to be a governor of the asylum; and of any correspondence that took place upon the same subject in the year 1876 or 1877 between the Mayor of Limerick and either the Chief Secretary or the Inspector-General of Lunatic Asylums.

Sewage Strata in Rivers.

At the last meeting of the Royal Irish Academy Dr. L. Studdert read a paper giving the results of a chemical examination of the mixed waters of the estuary of the river Liffey. Dr. Studdert said that the object of this examination was to ascertain the proportional intermixture and comparative states of the surface and deep waters in the Liffey estuary, at different states of the tide. It was found that from surface to bottom the sewage matter decreases, while the sea water increases in a given measure of the waters. A large proportion of the sewage discharged into the Liffey appears, at flood tide and in dry weather, to be contained in the first inch of surface, which, under the summer sun, would account for the noxious vapours emitted. Much of this superincumbent sewage was found forced up by waves or wind as far as 250 yards above any city outfall. The like foul deposit is reported to be thrown up stream from the mouth of the intercepting sewer constructed in the Thames below London.

The Health of Dublin.

The mortality of the city for the week ending February 23, was 33.1 per 1,000 of the population, while the death-rates of London, Edinburgh, and Glasgow, were only on the average, 24·0 per 1,000. This excessive unhealthiness of Dublin did not—as is usually pleaded in defence of the sanitary authorities—arise from respiratory diseases, for the mortality from these was as much as 19 less than those of the preceding week; but the deaths from dirt diseases were eight above the average for the same week of 10 previous years. The dirt and neglect of sanitation in the city grows daily worse. The remonstrances addressed to the Public Health Committee of the Corporation, have been suppressed. Every ingenuity is exercised to conceal from the public the abominable filth of the city, and the melancholy result of that filth is disease and death, while the "organs of public opinion," as the daily papers delight to call themselves, are too heavily overtaxed in recording the comings and goings of petty snobbery, to give attention to local questions of importance.

The Irish Zoological Society.

Judging from the Annual Report of this valuable Scientific (!) Institution, its final dissolution is put off at least until next year. True, it has increased its banker's debt, and has sold some of its animals to meet the deficit, and has touted with great vigour for public assistance within the last year. Were it not for these means of livelihood, it would be more than £200 worse in finance than last year. The gardens do not, it would seem, offer to strangers visiting even as much as they did last year, for the shilling and sixpenny admissions have fallen off. The stock of animals is ostensibly about the same as last year, but we are not told how many of the mammals are white mice, squirrels, and hedgehogs; and how many of the birds are peacocks, sparrows, and hawks. The Council has apparently foreseen the tightness of its finances next year, against which it has provided by selling the gift of a plesiosaurus made to it by Sir Philip Crampton, which will just wipe off its debt. What is to happen next year, when there is no plesiosarus to sell?

Persistence of the Retinal Image.

In the *Gazette Med. Ital.* Dr. Gorini makes allusion to supposed persistence upon the retina of images perceived during the last moments of life, which had been suggested as a powerful aid to medico-legal investigations by reproducing in the eye of the victim the image of the place of the murder and of its perpetrator. Dr. Gorini has no belief in this, but he experienced in himself a phenomenon which tended to shake his conviction. In the middle of the night he was lying down reading the page of a certain book and fell asleep for, he believes, an hour. On awaking he saw the wall, which was opposite to him, lit up by his lamp and covered with the type-forms of great size, forming words regularly arranged and separated by lines exactly as was the book which he was reading when he fell asleep. Not only could he distinguish the text, but he saw also the marginal notes in smaller character. The whole appearance was vague and dim, but he could not doubt that it was the image of the page which he was reading at the instant of sleep which he now saw. This strange apparition persisted for about twenty seconds, and, during this time, it was reproduced each time that the eyes were closed and reopened.

Treatment of Diphtheria by Turpentine Inhalations.

Dr. C. Edel, of New York, strongly recommends turpentine inhalations in the treatment of this disease. Since, he says in the *Medical Record*, the treatment of diphtheria by steam inhalation gives relatively the best results, he resolved to combine this method with a local disinfectant. For this purpose he uses Tiemann's steam atomizer in the following manner: He has the boiler half filled with water, and about 15 drops of the oil of turpentine before each inhalation, and then closes it. As soon as the vapour escapes, the patient is placed at a distance of three inches from the mouthpiece of the instrument. The inhalations are made every hour for about ten minutes, day and night. This treatment he has adopted in a number of cases with the most favourable results. Recent cases were cured in twelve hours, the temperature being reduced, and the sores in the throat becoming quite clean. The medicated inhalations also appeared to hasten the separation and expectoration of the membrane.

Factories and Workshops.

In Committee on the Factories and Workshops Bill, on Thursday, the 21st, Dr. Kenealy, objecting to clause 3, said that it did not provide sufficiently for the ventilation of factories and workshops, and alluded to the mortality among the operative potters of Hanley owing to this defect. In France many lives have been saved and diseases averted by efficient ventilation. Mr. Cross explained that under the provisions of the last Factory Act the powers of the inspectors had been much enlarged, by which considerable improvement had been effected, with beneficial effect in the prolongation of life. He would, however, consider the suggestion as to the desirability of giving further powers to the inspectors. Mr. Campbell regretted that the means for ventilation provided for the workpeople were not made use of as they ought to be. On Monday, the 25th, further progress was made with this Bill. On clause 27 some opposition was raised to the proposal that children on obtaining employment in another factory shall be freshly certified by the factory surgeon. Dr. Lush said that instead of diminishing the powers of the certifying surgeons he should like to see them increased very much. The clause was ultimately agreed to. On clause 38, which relates to the prohibition of children and young persons being employed in trades of a noxious character, Mr. Tennant desired to see other trades included in the schedule of the Bill, on the score of being injurious to health. Mr. Cross replied that it would not do to hamper trade too much. The clause was therefore agreed to.

Longevity of Medical Men in the Olden Time.

We find in the *Union Medicale* note of a letter written in 1705, by Jean Jacques Baier, Professor of Medicine at Atladorf, under the title "De Longevitate Medicorum.' He classifies the ages of 76 doctors of that day in the following table :—

From 70 to 79 years	.	.	10
„ 80 to 89 „	.	.	40
„ 90 to 99 „	.	.	10
„ 100 „	.	.	1
Past 100 „	.	.	6
Total	.	.	76

Hippocrates lived to 104 years, Leonicene to 106, Rhasès 120, Marcus Gallus, physician to Charles V, to 129, and Averrhœs to 130.

The Queen's University in Ireland.

A meeting of the Senate of the Queen's University was held on the 1st of March, the following examiners were appointed :—Thomas W. Grimshaw, M.D., Physician to Steevens's Hospital, Consulting Physician to Cork Street Fever Hospital, examiner in medicine ; William MacCormac, F.R.C.S.E., Surgeon to St. Thomas's Hospital, London, examiner in surgery ; Professor Kinkead, Professor of Midwifery in Queen's College, Galway, examiner in midwifery ; J. W. Moore, M.D., Physician to the Meath Hospital, and Cork Street Fever Hospital, examiner in medical jurisprudence.

Venesection in the Old Times.

It would seem that in the last century, even crowned heads were the victims of the vilest quackery, for we find in the *Union Medicale*, a record of the death, at Versailles, on the 19th of Feb., 1733, of the third daughter of Louis XV, at the age of five years. The following is the contemporary note respecting her medical attendant :—

"About twelve years ago, Bouillac, a Gascon, arrived at Versailles, and began the practice of medicine. He was then so poor that his whole possessions did not amount to £20. He managed shortly to attach himself personally to M. Regnier, the Procureur of the King, to whose house he went each morning to examine the *pot de chambre*. He became before long physician to the hospital, with a salary of £300, and was at last placed in care of the royal children. When the child, who died, fell sick, Bouillac commenced his treatment by bleeding her in the arm, and followed it up by three more venesections in the foot, in each of which he took three vessels (*palettes*) of blood.

The Hunterian Society.

At the recent annual meeting of the Hunterian Society the following gentlemen were elected officers for the ensuing year :—*President*—T. B. Crosby, M.D. *Vice-Presidents*—Walter Moxon, M.D.; J. McCarthy, M.B.; Buxton Shillitoe, Esq.; G. Lichtenberg, M.D. *Orator*—W. Rivington, M.S. *Trustees*—H. F. Fothersby, M.D.; D de Berdt Hovell, Esq. *Librarian*—P. L. Burchell, M.B. *Secretaries*—R. Clement Lucas, B.S.; Stephen Mackenzie, M.D. *Council*—J. E. Adams, Esq.; Fletcher Beach, M.D.; A. E. Durham, Esq.; J. R. Fendick, Esq.; R. Fowler, M.D.; T. Greenwood, M.D.; A. Galabin, M.D.; C. R. Nicoll, M.D.; A.H. Smee, Esq.; G. J. B. Stevens, Esq.; W. C. Toulmin, Esq.

The annual dinner of this Society was held at the "Albion," on the 22nd ult, when the retiring President, Mr. A. E. Durham, took the chair. He was supported by Professor Owen, the President of the Royal College of Surgeons, the President of the Medical Society, and many other distinguished members of the medical profession.

Ostrich Pepsine.

In the *Revue des Deux Mondes* there has been published an article which contains the following statement :—

"After hunting the ostrich in the Pampas, care is taken to put the stomach aside, in order to collect the pepsine which it contains. It is asserted that the stomach of that bird is noted for its remarkable power of digestion. The abundance of pepsine to which it owes this faculty has created, amongst the Indians, a singular branch of trade. They dry it and sell it, literally, at its weight in gold, an it is used to restore deranged digestion."

A Linear Scarificator.

A little instrument has been introduced by Mr. Malcolm Morris to facilitate Dr. Balmanno Squire's treatment of port-wine marks. It has been constructed by Mr. Hawksley, of Oxford Street, and consists of twenty-four minute lancets set together in a brass case, the points of the lancets being protruded through an outer case by means of a screw, each revolution being equivalent to one-thirtieth of an inch.

Our Reports on Rabies and Hydrophobia.

THE labours of the Commission we appointed to report on "The Nature and Treatment of Rabies," are now concluded, and we may fairly congratulate them on the result of their work.

Commenced in our issue of Oct. 24th, 1877, it has appeared in successive numbers of the MEDICAL PRESS AND CIRCULAR until last week, when the subject was thoroughly exhausted. The mass of facts and information now laid before the profession in a condensed and highly interesting form, cannot but prove invaluable, not only to other workers in this field, but to all interested about this peculiar disease.

These reports have cost much perseverance, labour, and time, and we have the satisfaction of knowing that they have been appreciated to such an extent, both by the press and the profession, at home and abroad, as to encourage us to reproduce them in book form, with some valuable additions. Our contemporary, the *Doctor*, in its last issue, says—"The writers of the elaborate report in the MEDICAL PRESS AND CIRCULAR, from which we have already twice made extracts, have brought to a conclusion their long list of carefully-analysed cases. This laborious work is a credit alike to the writers and the journal which publishes it."

Stewart Institution for Imbecile Children in Ireland.

AT a meeting of the Managing Committee of this valuable charity on last Monday week, Mr. Pascal Law attended, and handed over securities amounting to £3,165, to form the nucleus of a fund for the erection of an additional wing to the new buildings which are about to be opened at Palmerstown, in the county Dublin.

A New Source of Atropine.

A NEW source of atropine has been noted by Dr. J. Tweedy, of the Royal London Ophthalmic Hospital. The alkaloid was derived from an Australian plant—the *Duboisia myporoides*—of a tribe midway between the *Solanaciæ* and the *Scrofulariaciæ*, and the physiological properties were investigated by Dr. Sydney Ringer. The alkaloid would seem to be in all respects identical with atropine.

Manchester Hospital Charity.

THE Hospital Sunday and Saturday collections at Manchester, which have just taken place, do not compare favourably with previous years. The accounts have not yet been fully made up, but it is feared that the former will show a deficiency of at least £1,000, and the latter of £500.

Death of M. Voillemier.

THIS illustrious member of our profession died last week, of an attack of apoplexy, which had produced complete hemiplegia and loss of consciousness. He graduated as Dr. in 1842, but had then, during his studentship, distinguished himself by the publication of a memoire upon an epidemic of puerperal fever which had invaded the Clinical Hospital. His writings on luxations of the wrist, and upon fractures of the inner extremity of the radius have also been highly esteemed, and he was noted as the author of a work on "Diseases of the Urinary Organs." In 1844, the competition for the central department opened to him the doors of the hospitals, and he was promoted at length to the Hotel Dieu, where he has acted for the last four years. He was a commander of the Legion of Honour, and a member of the Academy.

Attar of Roses.

SOME idea of the costliness of the preparation of this article may be formed, when it is considered that to make one pound of attar 3,000 lbs. of blossoms are required. The principal rose farms (says *New Remedies*) are situated in the province of Kezanlik, in Roumelia, at the foot of the Balkan Mountains. The only rose cultivated for its scent is the Provence or cabbage rose. The rose harvest begins in the middle of May, and lasts for twenty-five days or so. The flowers are gathered before sunrise and the process of obtaining the oil is carried out by noon of the same day. The amount of otto is greatest when the temperature at the time of distilling is low, and *vice versâ*. When the weather is warm there is abundance of bloom, but the yield of otto is less; favourable weather is therefore better than large crops of blossoms. It may not be a fact generally known that the attar of roses, although made from that flower, has not its scent. The processes for obtaining the scent of any given flower are described under the terms "enfleurage" and "maceration." Distillation altogether fails to secure the specific perfume of the flowers from which scents are made.

THE rates of mortality last week in the four principal cities of the United Kingdom were London 26, Edinburgh 26, Glasgow 22, Dublin 34 per 1,000 of the population. In the other large towns, Brighton 32, Plymouth 32, and Norwich 37, showed the highest death-rate. Leicester was in the most favourable position with 15 per 1,000.

Correspondence.

THE ANTI-VIVISECTIONISTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nothing is more common than for men to condemn the very same action in others which they practice themselves whenever occasion offers.

"A fox and a cat, having made a party to travel together, beguiled the tediousness of their journey by a variety of philosophical conversations.

"'Of all the moral virtues,' exclaimed Reynard, 'mercy is surely the noblest! What say you, my sage friend, is it not so?' 'Undoubtedly,' replied the cat, with a most demure countenance; 'nothing is more becoming in a creature of any sensibility than a compassionate disposition.'"

"While they were thus moralising and mutually complimenting each other on the wisdom of their respective reflections, a wolf darted out from a wood upon a flock of sheep which were feeding in an adjacent meadow, and, without being in the least affected by the moving lamentations of a poor lamb, devoured it before their eyes.

"'Horrible cruelty!' exclaimed the cat; 'why does he not feed on vermin, instead of making his barbarous meals on such innocent creatures?' Reynard agreed with his friend in the observation, to which he added several very pathetic remarks on the odiousness of a sanguinary temper. Their indignation

was rising to its warmth and zeal when they arrived at a little cottage by the wayside, where the tender-hearted Reynard immediately cast his eye upon a fine cock that was strutting about the yard. And now, adieu moralising! he leaped over the pales, and, without any sort of scruple, demolished his prize in instant. In an the meanwhile, a plump mouse, which ran out of the stable, totally put to flight our cat's philosophy, who fell to the repast without the least commiseration."

The anti-vivisecticnists, who are so mightily indignant and wrathful against the practice of vivisection, being so much overcome by their refined feelings, and their extremely acute sensibility, would do well to peruse and ponder over the above fable, where they (of course, I mean those remarkably humane anti-vivisectionists) are aptly personified by those two excellent specimens of tender-heartedness—viz., the fox, who is brimful of that noble virtue mercy; and the cat, whose tender conscience revolted at cruelty; for I seriously fear they have abstracted the low cunning of the fox and the sinister maliciousness of the cat in their proceedings against *that* which is done in the cause of *real* humanity, and using as a cloak for their misrepresentations and exaggerations, the pretended mercy of the former and the counterfeit tender conscience of the *latter*, in order to promote and further their most humane intentions as regards protecting certain dumb animals, while they very considerately run others to death in the hunting-field. This without doubt, demonstrates their *remarkable* humanity, and makes one rather dubious as regards their sincerity.

These anti-vivisectionists, strange to say, object to experiments being performed on animals for the sake of physiological research and the welfare of mankind, though they yet do not declaim against fox-hunting, chasing hares to death, clipping dog's ears, and curtailing these animals into the bargain; they have no commiseration for the hunted otter, whose dying agonies give such pleasure to his humane tormentors. For the sake of their stomachs, they do not demur at calves being bled to death in order that they may be provided with veal of an agreeable appearance and pleasant to the palate.

Do they protest against the castration of stallions? Not at all, otherwise how could many of these humanitarians indulge in equestrian exercises, or ensconce themselves in luxurious carriages? Do they ever raise a voice against the castration of bulls and similar barbarous customs? Of course, preventing such *necessary* cruelty would deprive them of many luxuries and comforts with which they would be loath to part. Yet we see many of them, after witnessing a stag torn to pieces, and enjoying the sight, under the name of sport, with a fiendish glee, proceed with all the effrontery imaginable to address a public meeting upon the supposed iniquities of vivisection, and weep crocodile tears over imaginary cruelties.

"A wolf," says Plutarch, "peeping into a hut where a company of shepherds were regaling themselves with a joint of mutton, exclaimed—'Lord, what a clamour would these men have raised if they had caught *me* at such a banquet.'"

I cannot refrain from asking these philanthropic anti-vivisectionists how far they can reconcile themselves to such self-evident inconsistencies, and would it not be far better for them, before meddling with matters which, practically, do not concern them, and of which they are decidedly ignorant—to discard such detestable hypocrisy?

"Unfortunately, too many are apt to condemn in others what they practise themselves without scruple."

Yours, etc.,

ANTI-KOOM-POSH. (*a*)

THE ADMISSION OF WOMEN TO THE BRITISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that the medical education of women is, both in other countries and at home, an accomplished fact, it is not surprising that new difficulties should seem to have arisen from this remarkable phase of modern existence, as compared with the ancient ideas as to women's place in society.

I would venture to hope that those very able ladies who have already secured a place among the members of the Association may not be forced to leave it, on account of the sudden burst of instinctive feeling against their presence in certain sections of the Association. Doubtless, for some time to come, it may be quite out of the question to suppose that men and women can discuss in detail many of the topics which arise in practical medicine or surgery. In the meantime, therefore, women who are members of the Association might discuss the questions *they* are interested in, in a room of their own.

Many points in hygiene and medical politics, however, could with advantage be discussed in the presence of lady practitioners, such as the alcohol question, or that of the causation of fever, &c. As to any longer keeping women out of the profession, that is impossible.

Your obedient servant,

C. R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S. Eng.

17 Woburn Place, W.C., Feb. 27th, 1878.

(*a*) "Koom-Posh" signifies "bosh," *vide* Lord Lytton's "Coming Race."

Literature.

ZIEMSSEN'S CYCLOPÆDIA OF MEDICINE. (*a*)

WHEN we consider the small space devoted in our best text-books and standard works on medicine to diseases of the peripheral cerebro-spinal nerves, we cannot but be struck with astonishment when we see a volume of the large dimensions of the present work devoted to them. This treatise must be regarded as a series of purely clinical studies; it offers us no new pathological facts in explanation of the interesting class of cases which it describes. After enumerating the well-known conditions occasionally found associated with neuralgia—such as the flattening and atrophy of the nerves, degeneration of nerve fibres, swelling and hyperæmia, inflammation and thickening of the neurilemma, dilatations of both arteries and veins of nerve trunks, cicatricial indurations and growths in them, together with similar changes observed in the central nervous system—the author concludes, with Anstie, that these must be considered as generally accidental, and only rarely as factors in the production of neuralgia.

The author arranges his material as follows:—1. Neuroses of the sensory nerves: (*a*) Neuralgia in general; (*b*) Neuralgia of the individual nerves; (*c*) Anæsthesia. 2. Neuroses of the nerves of special sense, limited to the nerves of taste and smell. 3. Neuroses of the motor nerves, in which he treats of spasms, cramps, tetany, contractions, paralysis in general, and of the muscles supplied by particular nerves or groups of nerves. Finally, the anatomical diseases of the peripheral nerves are described—namely, the diseases associated with distinct structural changes, such as hyperæmia, inflammation, atrophy, and hypertrophy.

In the chapter on neuroses of nerves of special senses, we are surprised to find none of the auditory or optic nerves described. This appears to us a strange omission, for tinnitus, nervous deafness, auditory vertigo, photophobia, and other affections of these nerves are among the most common neuroses. Again, in the chapter on neuralgia, no allusion is made to the treatment by nerve-stretching introduced by Mr. Callender, and which has been employed with success in many obstinate cases by Continental as well as English surgeons.

Notwithstanding these and some other omissions, the practitioner will find this volume a very valuable book of reference in the management of the obscure and troublesome diseases of which it treats. It is full of valuable indications for treatment and diagnosis. This is especially the case with regard to the employment of electricity, in connection with which Professor Erb has previously given many valuable contributions to medical science. It contains, moreover, not only the experience

(*a*) Ziemssen's "Cyclopædia of Medicine." Vol. xi. "Diseases of the Peripheral Cerebro-Spinal Nerves." By Prof. Wilhelm Heinrich Erb. Translated by Mr. Henry Power. Sampson Low and Co., Crown Buildings, 188 Fleet Street. 1876.

and observations of the author, but a good account of the work of others bearing upon these diseases.

The English translation is the work of Mr. Henry Power. Having said this, it is unnecessary to add that the English is perfect, and bears no traces of the German idioms and arrangements of sentences which frequently prove so obscure to the English reader.

A MEDICAL DIGEST. (a)

THE medical literature of our day has become so overwhelming, and the time at the disposal of the practitioner for bibliographical study is so greatly curtailed by the exigencies of practice, that the cataloguer has come to be a benefactor to workers in our profession—nay, even a necessity to those who desire to follow out the subject which they have taken in hand. As a rule, the authors who are in highest repute are not allowed the opportunity of communicating to the profession the invaluable outcome of their experience and their thought, because the hours devoted to authorship must be snatched either from needful rest, or from their watching over clamorous and lucrative patients. Therefore their literary efforts are usually confined to the pages of medical periodicals, where they secure a widespread publicity and a multitude of readers, but get nothing more than an ephemeral attention. To rescue these contributions to medical science, is the valuable function of the cataloguer, and inasmuch as the task is unhonoured as a work of science, unremunerative as a matter of business, and somewhat bewildering and uninstructive as a matter of study, the preparation of such indices is essentially the duty of a publishing society.

Of the many valuable contributions to medical literature, of which the New Sydenham Society has been the parent, not one possesses more sterling practical value than the "Medical Digest" of Dr. Neale, which they have just issued, albeit it takes no position as a work of science.

Dr. Neale has, by this labour, placed his industry and research upon a pinnacle for the admiration of all men, especially when we consider that the book was prepared without any commission from the Sydenham Society, or from any other publisher. It occupys nearly 700 pages, and includes within its covers a reference to every contribution upon every subject which has found a place in the leading English medical periodicals of the last forty years. The number of journals at Dr. Neale's disposal was necessarily limited, and there is, therefore, much outside his digest as well worthy of reference, as those articles which its pages include, but as it stands, the work is apparently thoroughly well done, and of incalculable advantage to the seeker for the ideas of other men.

Dr. Neale has given us enough of perfection to inspire regret that the Sydenham Society did not undertake a more comprehensive work of the same sort, as they once thought of doing. There can be no reason why, at some future time, with Dr. Neale's work as a basis, they should not give to the profession something like a complete index to the periodical medical literature of the English language within the last quarter century.

THE DENTAL BILL.

WHEN we first called the attention of the profession to this measure, we did so under the strong impression that it had been worded by those who framed it in so clumsy a way as to convey a different meaning from that which was intended, and that it was introduced by Sir John Lubbock on the faith of the representations of its promoters without careful perusal or consideration of its provisions.

The experience of a fortnight and the public statements of Sir John Lubbock have convinced us that we had given credit to the supporters of the measure for more discretion and less audacity than they possess, and that every objectionable point in the measure was deliberately included in it, and intentionally offered to Parliament for its acceptance. It is now avowed that Mr. Tomes—its prime mover—and Sir John Lubbock desired to admit to registration as a "dental surgeon" every person who could produce upon the 1st of January, 1879, a brass plate as his diploma—that they intended to give that person power to prosecute everyone who was not included within the sacred pale of registration, even to a fully qualified surgeon who might denote himself a "dental surgeon"—that they did not contemplate requiring from dentists any evidence of professional competency whatever in the present, and only a nominal evidence of knowledge or study in the future. But even this is not the full limit of Mr. Tomes's and Sir John Lubbock's complaisance, for we find in the *Pharmaceutical Journal* of last week the learned baronet's explicit declaration that he will gladly support an amendment having for its object the admission of all those persons who can say that they "have practised dentistry in connection with pharmacy"—in other words, every druggist in the kingdom.

We are told, truly, that Sir John Lubbock has consented to reserve for surgeons the use of the titles "surgeon-dentist" and "dental surgeon," and has, furthermore, graciously pleased to admit qualified surgeons to the noble roll of dental druggists and door-post dental mechanics, a condescension which we stigmatise as nothing less than an insult to the professional and social position of the members of our profession. For his conception that surgeons would hasten to record their names in such a list Sir John Lubbock may perhaps be excused, but those who have prompted him on the subject must be emphatically censured, inasmuch as their association with medical men should certainly have taught them better.

We have said enough to make it obvious that the Bill cries out for the unanimous and energetic opposition of surgeons of all classes and in all places, and of dental surgeons in particular; but we hope it will not be considered a sufficient concession that surgeons should be allowed the same privileges as their druggists.

We think it well that our views on this subject should not be mistaken, and therefore state them categorically, trusting that the profession will—in the public as well as the professional interest—concur with us in opinion. We hold that dentistry, in accordance with public necessity, has separated itself so completely from general surgery, and has developed into so distinct and important a speciality that it is proper that it should be now recognised as a separate profession. We are convinced that it is needed for the public advantage that dentists should be thoroughly competent and well educated in their speciality, and that it is eminently desirable that the public should be afforded a means of distinguishing between dangerously ignorant persons and those who understand their business. We recognise in dentistry so much that is outside the domain of surgery, and nevertheless essential to the speciality, that we cannot claim for surgeons even a theoretical competency for dental practice, unless qualified by special additional education; and we, therefore, do not ask for them either recognition or registration as dentists unless they shall have proved their special knowledge of this branch of surgery. The necessity for such a speciality, proved by the public demand for dentists, constitutes, to our mind, a distinction between dentistry and ophthalmology, which is a branch of surgery required by but few, and involving no art other than that which surgeons are taught. We acknowledge the propriety of separating skilled dentists from druggists and other pretenders, but, if circumstances make this separation impossible, we deprecate emphatically any form of registration or classification which would raise the incompetent to the same level as the skilled, and deprive the public of the means of judging between the two. Finally, we protest against the establishment of a sham dental qualification, sold by any college to all purchasers at any price it will fetch, and on

(a) "The Medical Digest." Being a means of Ready Reference to principal Contributions to Medical Science during the last twenty years. By Richard Neale, M.D., Lond., Member of the Dutch Medical Society of Batavia. London, New Sydenham Soc. Royal 8vo, pp. xiii, 650.

any educational terms at which it can be got. If we cannot have a real test of knowledge, and if we must recognise as dental surgeons all sorts of tooth-drawers and metal workers, we ask at least that matters shall be left as they are, and that these persons shall rest on their own merits, and not be raised to a surgical position by means of a legal registration which is of no value but to mislead the public. Certainly, there can be no hurry with this Bill at present, for if it is desirable to create a registrable dental license, that can be much better done by the Duke of Richmond's Medical Reform Bill, which is just about to be introduced, in which one clause would effect what is required much more effectively than a special bill can do.

In these views we are glad to find ourselves supported by the profession in Scotland, as represented by the Edinburgh College of Surgeons. That body has petitioned Parliament against the measure—the petition having reached us as we were going to press—and we doubt not that the whole profession of the United Kingdom will join in our protest against such mischievous legislation.

King's College Hospital.—At the annual Court of the Corporation of this institution, held on Thursday last, it was stated that during the past year, whilst almost every other charitable institution in the metropolis had suffered, the subscriptions to the King's College Hospital had not only not fallen off, but had somewhat increased. The report showed that the several departments were in a highly satisfactory condition, and that a considerable addition had been made to the number of beds by the construction of a new ward and the re-opening of another which had been closed for many years. The income of the hospital for the past year amounted to £10,250. The total amount expended for the ordinary purposes of the hospital was £13,361, as against £11,117 in 1876. The cost of alteration and enlargement was £2,513, yet, notwithstanding this large extraordinary expenditure, the capital account of the Corporation had been increased by £2,336, from legacies invested during the year. A fund which had been opened for the establishment of a convalescent home now amounted to upwards of £5,000, mainly owing to the personal exertions of Dr. Guy and a committee of ladies.

Fire in a Lunatic Asylum.—A new wing of the Richmond Lunatic Asylum in Dublin took fire on Monday evening. It was occupied as a male ward, and there were in it 200 patients, including 60 who were in hospital. The inmates were all removed to other departments. No water being available, the fire brigade was nearly useless. The fire continued until a late hour of the night, but no life was lost. The wing was three storeys high, and it was ultimately cut away from the adjoining structure.

NOTICES TO CORRESPONDENTS.

QUERIST.—Ethyl-benzine is the same thing as zylol, also sometimes called zylene; it is one of the hydro-carbons formed from coal-tar naphtha. It has been found useful in the treatment of variola, acting, it is supposed, as a disinfectant of the blood.

DR. P.—Unless the coroner had sufficient grounds for suspicion he could not legally compel you. The coroner's law is altogether in a most unsatisfactory state, and with you we regret that there appears at present no prospect of the subject being legislated upon.

DR. SAYRE, New York.—Communication received as were going to press; will be referred to in our next.

DISPENSARY MINUTE BOOKS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Can the hon. sec. to a dispensary committee retain in his own custody the minute-book?

A committee meeting was held near the dispensary, the secretary asked the dispensary doctor for the book, and then afterwards retained possession of it.

Yours, &c.,
A SUBSCRIBER.

[Certainly he not only can, but must. Articles 12 of the Dispensary Regulations (page 242, "Irish Med. Directory") makes the hon. sec. responsible for the "safe custody *of the dispensary*, of the books, papers, documents, and correspondence of the committee." The hon. sec. cannot keep the book at home, but he must not leave it in any one else's care than his own.—ED. M. P. & C.]

DR. WILLIAMS.—1. Surgeon-General Gordon's "Lessons in Military Hygiene and Surgery from the Franco-Prussian War" will be for you the most reliable, and at the same time the most modern guide in case of war. 2. "Parke's Hygiene." 3. We know of no separate work on the subject; there are, however, chapters sufficient for your purpose in the two books before mentioned.

AN Evening Meeting of the Pharmaceutical Society of Great Britain will be held this day (Wednesday) at 8 o'clock.

BATHS FOR SUBACUTE RHEUMATISM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Could you inform me as to the suitability of baths for a fever patient, æt. 28, unmarried, subject to attacks of subacute rheumatism, and, if advisable, what baths in Germany would you recommend?

I am, yours faithfully,
"DELTOID."

[Baths would, we doubt, be of use in such a case as you mention. Among German bathing places suitable for your patient we may name Aix-la-Chapelle (Aachen), Wiesbaden, Wildbad, Baden-baden, &c. You should consult Dr. T. More Madden's work, "The Spas and their Use" (third edition), and Dr. Josef Seegen's "Handbuch der allgemeinen und speciellen Heilquellenlehre," published at Vienna in 1862 by Wilhelm Braumüller.—ED M. P. & C.]

THE IRISH FASTING GIRL.—A paragraph appeared lately in the *Irish Times* in which it was stated that "There is at present living at Ballywalter, co. Down, a young woman who, for the last six months, has not partaken of solid food of any description. She receives a little whisky and water occasionally, and spends a greater part of her time in sleep." We have made inquiry, and ascertained that no person answering this description is known either to medical men or relieving officers in the neighbourhood of Ballywalter.

DR. OGSTON.—Your work has been duly received, and will be noticed as soon as space permits.

METROPOLITAN HOSPITAL SUNDAY FUND.—An announcement in our advertisement columns to-day requests that the authorities of hospitals and dispensaries desiring to participate in this year's Fund should send in their applications on or before the 9th inst. to the Secretary, Henry Custance, Esq., at the Mansion House.

ROYAL INSTITUTION.—Thursday, March 7, at 3 p.m., Professor Dewar, "On the Chemistry of the Organic World."

LINNEAN SOCIETY.—Thursday, at 8 p.m., Dr. Patrick Manson, "On the Development of Filaria Sanguinis Hominis, and on the Mosquito considered as an intermediate Host." Dr. T. Spencer Cobbold, "On the Life History of Filaria Bancrofti as explained by the Discoveries of Wucherer, Lewis, Bancroft, Manson, and others."

HARVEIAN SOCIETY.—Thursday, at 8 p.m., Casual Communications. Dr. T. S. Dowse, "On the Treatment of Syphilitic Disease of the Nervous System."

CLINICAL SOCIETY.—Friday, at 8½ p.m., Mr. Hulke, "Large Aneurism of the Left Subclavian and Axillary treated by Rest and a very limited Diet" (living specimen). Dr. Broadbent: (1) "Sudden Death from Effusion into the Pleural Cavity, without Paracentesis." (2) "Unusually rapid Effusion into the Pleural Cavity at the age of seventy-six; Paracentesis; Recovery." Dr. F. Taylor, "Unilateral Atrophy, with Muscular Spasm (Athetosis?)" (living specimen).

VACANCIES.

Dunfanaghy Union, Falcaragh Dispensary.—Medical Officer. Salary, £100. Election, March 22. (See Advt.)

Sligo Union, Carney Dispensary—Medical Officer. Salary, £120. Election, March 13. (See Advt.)

APPOINTMENTS.

BUSZARD, F., M.D., Physicician to the Northampton General Infirmary.

COLEY, F. C., L.R.C.P.L., M.R.C.S.E., House Physician to the Hospital for Women.

COOKE, E. M., M.B., M.R.C.S.E., Medical Superintendent of the Wilts County Lunatic Asylum, Devizes.

FAYRER, Sir J., M.D., F.R.C.P.L., F.R.S., K.C.S.I., Consulting Physician to Charing Cross Hospital.

Marriages.

BLAIR—PRITT.—Feb. 28, at St. John's Church, Preston, Lancs, Robert Blair, M.D., C.M., of Goole, Yorks, to Emma, eldest daughter of Henry Pritt, of Preston.

M'DONNELL—M'DONNELL.—Feb 27, at Dunmore, co. Galway, Joseph M'Donnell, L.R.C.P., &c., to Annie, youngest daughter of Martin M'Donnell, Esq.

Deaths.

ANDREWS.—On Feb. 29, at Walton Park, Walton, Liverpool, George Andrews, L.R.C.P.L., M.R.C.S.E., L.S.A., aged 33.

CLANCY.—On Feb. 21, at Mitchelstown, co. Cork, Thomas Clancy, M.D.

GURDON.—On Feb. 3, at Hadleigh, Suffolk, Theophilus Goate Gurdon, M.R.C.S.E., aged 64.

LLOYD.—On Feb. 14, at Llangefni, John Hughes Lloyd, M.D., aged 61.

MILLER.—On Feb. 11, at Hulme, Manchester, Charles Miller, L.R.C.S., aged 75.

MONCK.—On Feb. 15, at Hucknall, Notts, Charles Edward Beresford Monck, L.R.C.S.I., aged 38.

MUNGALL.—On Feb. 22, at Foulford House, Cowdenheath, Fifeshire, Robert Mungall, M.D.

NAIRNE.—On Feb. 22, at Kennington Road, Charles Nairne, M.R.C.S., aged 73.

NEARY.—On March 1, at Howth, co. Dublin, Kate Elizabeth, the beloved wife of Dr. B. J. Neary.

SWAIN.—On Feb. 28, at her residence, Devonport, Harriett, wife of Wm. Paul Swain, F.R.C.S.

THOMAS.—On Feb. 12, at Horton, Yorkshire, Abraham Thomas, L.S.A., aged 79.

WHITFIELD.—On Feb. 28, at his residence, Eastbourne, A. Whitfield, M.R.C.S., aged 43.

OBSERVATIONS ON THE SYMPTOMS ARISING FROM THE ASCARIS LUMBRICOIDES.

By EVAN MARLETT BODDY, F.R.C.S., F.S.S.

So various, and sometimes apparently dangerous, are the symptoms which arise from the irritation caused by the presence of ascaris lumbricoides in the small intestines, and so remarkably do they simulate certain diseases and lesions to which the human frame is subjected, both in infancy and adult life, that I am tempted to think that a few observations will not be considered a work of supererogation; for these parasites are so frequently present in the intestinal canal, irrespective of age, without our being cognisant of the fact, that we are very prone to be in error as concerns our diagnosis, owing to the ambiguity of the symptoms; besides, they give rise to such distressing sensations to those unfortunate individuals who are afflicted with them, as to cause their diagnosis to be extremely difficult and unsatisfactory; partly owing, I need hardly say, to the inaccurate accounts of the sufferer. Also, I am inclined to think that these deceptive parasites (for such they really are) are treated by many authors as if they and their ravages were not of much importance, and accordingly in their works these worms and the symptoms arising from them, are treated of very lightly, and superficially compared with their disquisitions on other subjects in relation to medicine.

In the course of my remarks I shall cite some highly interesting and instructive cases which on various occasions have come under my own immediate observation, and I shall also mention the course of treatment which I thought it necessary to pursue.

I do not think we shall be going over well-trodden ground, for the subject is far from being exhausted; besides, I think it deserves our serious and more than ordinary attention, for many individuals are afflicted, indeed, I may say, tormented, with these parasites without being aware of their presence; and as no notice is taken of the alvine excreta by the sufferers, nothing which leads to their discovery can be elicited from them.

I have noticed that by far the greater number of cases of intestinal parasitical irritation occur in the dirty haunts of the poor of large towns, and among the labouring classes of rural districts; but why they should be so remarkably prevalent in the squalid dwellings of town-poor and yet be almost equally so in spots where Nature revels in beauty and loveliness, I leave others to divine; I have found such to be the fact, but whether it is borne out by the experience and observation of others I know not; I have invariably noticed it, and I have had many opportunities of so doing. The symptoms are also sometimes so grave and so variable that many are apt to confound them with those which are entirely dependent on diseases dangerous and incurable; for I have known some cases present such curious and varied phases, so many conflicting and deceptive symptoms, as almost to defy a correct diagnosis; and I think more especially so in the female sex, of about, or beyond the age of puberty, for then we are very nearly certain to have some uterine complication, or a hysterical tendency which is aggravated by the irritation resulting from these parasites with which we have to deal, besides the weak state of the health, which is generally present in intestinal parasitical irritation.

Indeed, in infancy, the symptoms are, as a rule, variable, for some may suddenly disappear to give place to others equally ephemeral, so that sometimes it is next to impossible to determine from what the child is really suffering; for one day there may be symptoms simulating to a marked degree some lung affection; next day, perhaps, the child is in a high state of fever, accompanied with cerebral excitement, with the temperature up to 104°; then, most likely, by the third day, all these symptoms have passed off and the child may appear tolerably well; on the fourth day, the case is equally perplexing, for some symptoms, perhaps, have cropped up entirely different, pointing, may be, to some other derangement.

Most likely we can gather no history of worms, for these parasites hold on to their intestinal habitation very tenaciously, and then, owing to the contradictory sym-

ptoms, the case is considered as of an intricate nature, and, consequently, no anthelmentic is administered until the ejection of a worm, by an effort of Nature, suddenly opens our eyes as to the real state of affairs.

I remember one very remarkable case which was admitted into one of the London hospitals, and which is aptly illustrative of these deceptive symptoms. The patient was a girl of about 13 years old, emaciated and weak; she had a continual dry hacking cough both night and day; the appetite was variable, though sometimes she would eat ravenously; at night time she was exceedingly restless and excitable, and in a high state of fever. The catamenia had not appeared. The case was diagnosed as commencing phthisis, though no abnormal sounds could be detected on auscultation, nor could any lesion be discovered by palpation. For a fortnight she was under treatment, the cough continuing as bad as ever, though she very much improved in physique and gained flesh rapidly. At the end of a fortnight two large round worms were passed with much straining; the cough now decidedly improved, and the child got better, and was soon after discharged.

This case was diagnosed by one whose diagnostic skill it would have been presumption to question, to be incipient or commencing phthisis; and I remember he evinced no little surprise at the speedy recovery of the patient after the expulsion of the worms, and at the rapidity with which the cough subsequently ceased.

This case to my mind is highly instructive, for it shows how the skill of an expert physician may be completely baffled by these parasites. There is not the slightest doubt, but that the worms were expelled solely by an effort of nature, for no anthelmentic was administered, as the case was treated as incipient phthisis is generally treated, for when the child had a slight attack of diarrhœa, an astringent was administered immediately,—however, the worms were ejected, and the child improved. We may, with a certain degree of justice, presume that there were other worms in the intestinal canal; but one thing is certain—the worms were the originators of the supposed phthisis, and the cough was, no doubt, gastric, and not pulmonic, for the lungs were diagnosed to be healthy by one who was fully competent to decide, though he asserted that owing to the incessant cough, the case was one of incipient phthisis.

Another peculiar case came under my observation not long ago of a similar nature, but it was complicated with a rash simulating that resulting from scarlatina simplex; so much so, that I was somewhat inclined at first to consider it as such, and treated it accordingly; the rash soon disappeared, but the dry hacking cough, foul tongue, and high temperature, accompanied with irregularity of the bowels, still continued, and the fever instead of abating increased, and the symptoms gradually assumed a typhoid character; at last the child vomited up a large round worm, and immediately experienced marked relief from its expulsion. I now changed my plan of treatment *in toto*, for I came at once to the conclusion, that as one worm had been ejected, others might be in the intestines, so I accordingly gave the child every night a powder, consisting of equal proportions of calomel and santonin, followed the next morning, by castor-oil; in three days, sixteen round worms of various sizes were passed *per anum*. The child now speedily recovered its previous health, the rash disappeared as rapidly as it appeared, and the cough left just as quickly.

This case is extremely interesting, as it exemplifies in a most remarkable manner the various deceptive symptoms devolving upon intestinal parasitical irritation, for there was the cough simulating that which is invariably present when the lungs are beginning to be consolidated by the formation and deposit of tubercles; there was the rash very similar to that which is present in scarlatina simplex, and there was the foul parched tongue, rapid pulse, hot and dry skin, high temperature, irregularity of the secretions, and nocturnal delirium. Now all these symptoms were what I call deceptive, for they pointed almost conclusively to certain diseases which were not present, and were simply dependent upon the irritation set up by these intestinal parasites.

Another case came under my observation with symptoms closely analogous to those indicative of acute hydrocephalus, with this difference—the pupils were of normal size, no worm had been detected in the excreta (on this point, I may say, the mother was most emphatic), so I had absolutely nothing to guide me in my diagnosis, save symptoms which, had I regarded, would have led me into error; but bearing in mind, however, those cases which had previously come under my notice, I gave the child some calomel and santonin, and by next morning four round worms had been passed: a few more powders of the same kind speedily removed the acute hydrocephalic symptoms, and the child rapidly recovered.

In other cases the symptoms were ambiguous and changeable, some of them assuming various phases daily, so that I could not arrive at any decided diagnosis, but the administration of calomel and santonin very soon elucidated what I may call the delusive phenomena of intestinal parasitical irritation.

Though these parasites are more frequently found in children, yet I have nevertheless known them give rise to such curious symptoms in the adult as to completely perplex the most skilful; sometimes they are similar to those arising from hysteria, and they have also simulated those to which dyspepsia gives origin: the most distressing nausea and headache are also caused by these worms, the presence of them being unknown, because none have been observed in the ejecta, and therefore, no treatment is of benefit, save the administration of an anthelmentic and a purgative. Frequently, on being consulted by patients suffering from extreme debility and lowness of spirits, I have discovered that nothing save the irritation set up by these parasites originated the deceptive symptoms and their distressing sensations.

We are well aware that infantile convulsions, in many cases, owe their origin to the irritation produced by these intestinal parasites, but that they should be provocative of convulsive attacks in the adult, or that they should produce fits analogous to epilepsy, or seizures of an epileptoid character, is a phenomenon not so generally known; in fact, it is so rare an occurrence, that we may designate it as a medical curiosity, a freak of disease, a deceptive symptom which one may say is significant of intestinal parasitical irritation; and as such, it deserves more than ordinary attention and comment. The following case to which I shall now draw the reader's notice, is a very remarkable and unique specimen, illustrative of this false epilepsy, or epileptoid fits, arising from the irritation resulting from the ascaris lumbricoides in the intestines; for the attacks were so frequent, obstinate and violent, that the patient, a girl of eighteen years, was pronounced by many medical men to be a confirmed epileptic, and that all further treatment would be fruitless in its results. Epilepsy, or convulsions resembling that disease, as a rule proceed from some irritation of the encephalon, or from some obscure lesion of the spinal cord, but in this case they were solely dependent on the presence of the ascaris lumbricoides, as the after results proved, for when the worms had been expelled through the means of an anthelmentic, the fits immediately ceased.

The seizures were an exact counterpart of epilepsy, yet we cannot justly consider them as such, on account of their originating from intestinal irritation; they were, as I have previously said, frequent, obstinate and violent, and on several occasions they were of such long continuance, that the presumed epileptic was much exhausted, and her constitution was visibly being undermined by the pertinacity of the attacks. On the termination of the seizures, especially when of a prolonged nature, she would lie in a comatose or semi-comatose condition, the duration of which would last for a day or two, then she would gradually revive, and to all appearance would be in perfect health. As I had the good fortune to see her during one

of the attacks, I was enabled to determine and judge for myself, and from its epileptoid character I should have considered it as a *bona fide* case of epilepsy, had it not been for many symptoms indicative of intestinal irritation and obstruction, such as the following :—obstinate constipation, foul tongue, an offensive breath, appetite variable, though sometimes voracious, especially preceding the attacks, catamenia normal, and the abdomen much distended. The mental capacities were of the average standard, and were not in the least impaired, though she had been afflicted with the attacks for the long period of six years ; the interregnum between each being of a longer or shorter duration, and her eyes, instead of presenting the dull heavy appearance which is usually to be seen in epilepsy, were bright, sharp, and intelligent ; this at once made me conclude that the attacks were not due to epilepsy, otherwise, considering the lapse of time, the eyes would have assumed the character more or less observable in true epileptics ; besides, there would have been a decided failing of the mental powers consequent upon the frequent repetition of the seizures, their severity, their obstinacy, and duration.

As no portions of the tape-worms had been discovered in the excreta, and as I was firmly persuaded that it was not a true case of epilepsy, I at once diagnosed the case as intestinal irritation resulting from the ascaris lumbricoides, and accordingly I administered six grains of santonin combined with an equal amount of calomel, to be followed the next morning by some castor-oil. Three large round worms, one a foot and a half in length, and about the thickness of a little finger, were speedily ejected, with wonderful relief to the patient. Continuing this treatment for a week she was happily ridded of her tormentors, and is now in complete health. She had one attack while under treatment, but the severity of it was considerably modified, the stupor lasting for one hour only, but after the bowels had been freely relieved, which occurred during the stupor, she was much better, and on reviving from its effects, she said she had not felt so well for years.

The peculiarity and chief interest of this case rests on the similarity existing between the convulsive attacks resulting from the irritation produced by the ascaris lumbricoides, and those arising simply from epilepsy ; its remarkable prolongation, and the rapidity of its cure.

Many reasons could be assigned for the extreme irritability of the nervous system, such as acute sensibility of the sympathetic, caused more or less by the movements of the parasites, or the spinal cord might have become peculiarly irritable, owing to this nervous system being complicated, and which perhaps, at certain periods, culminated in a fit, the frequency and severity of which depended either upon the condition of the alimentary tract, or mental excitability produced by the pneumogastrics being irritated through the medium of the ganglia of the sympathetic, but there is no doubt but that the ascaris lumbricoides were the direct or prime causes of the convulsions, and being so, it makes the case more peculiarly interesting, and especially as the convulsions simulated epileptic fits.

These examples I have mentioned as illustrating the deceptive symptoms arising from intestinal parasitical irritation are not only instructive, but they show us to a marked degree how easily one may be led into error in their diagnosis, and how the prognosis, instead of being hopeful, is of necessity doubtful and ominous, because the presence of the ascaris lumbricoides in the intestines is not discovered, and also the various, peculiar, and often conflicting, promiscuous symptoms which are many times apparently serious, mislead us, and the patient's health is considered to be in a precarious condition, when the administration of an anthelmentic would immediately cure the sufferer, and put to flight the grave symptoms which caused us to imagine life to be in jeopardy.

NOTES ON MIDWIFERY.

By THOMAS P. TUCKEY, M.B. T.C.D.,
Castletownroche.

1. THE POSITION OF THE PLACENTA RELATIVE TO SEX OF THE CHILD.

2. SPONTANEOUS EVOLUTION SUCCESSFULLY INITIATED.

THERE is no subject connected with physiology so interesting to my mind, and at the same time so obscure, as the laws which regulate reproduction. Why one woman will have no children which are not of the male sex, and another will have none except girls, while a third will bear them in equal proportion, or alternately male and female, is a question which has never been answered satisfactorily. Since I have been engaged in the practice of midwifery, I have never ceased labouring to throw some light on the subject. My labours have been too limited, and my experience of too short a time, to enable me to bring forward anything conclusive on the matter. I shall be satisfied if I have engaged the attention of those who have far greater opportunities than I am ever likely to have of elucidating the matter. I do not forget—and I hope I never shall—the caution of my venerated master, Mr. R. W. Smith, who was wont in his lectures to caution his pupils against rushing into print, and bringing forward a few facts as proofs of a pet theory, and who used to hold up as an example to those who have the *cacoethes scribendi*, the case of Harvey, who witheld from the world for so many years that discovery which has made him immortal, until he excluded every element of error from that grand law, which he knew to be indisputable. Harvey's discovery, however, was made in days when medical works were comparatively few, and journals fewer still—if there were any—and therefore any statement brought forward by a man of mark was likely—for good or ill—to influence for a long time his successors. We all know how long the classic medical writers of early times influenced the writings and practice of their successors, and how anything, at variance with preconceived opinions, was received with suspicion, if not with open opposition and derision. Harvey, doubtless, knew this, and therefore was more cautious in bringing forward his discovery, a discovery which he knew must revolutionise medicine. No such objection now holds, so numerous are the medical periodicals, that an error is no sooner put in print than that it is refuted ; while statements which are at first weak, are caught up by the numerous great minds of the medical world, and thoroughly sifted, and if true, placed on a firm and established basis ; if false, are relegated to the limbo of merited forgetfulness. I have less hesitation therefore in writing the following lines, knowing that my obscurity will prevent my doing any harm if I am wrong, and resting in the hope that if there is anything worthy of notice, some one with better opportunities than I have, will work up the subject, and bring forward more facts relative to the matter. It has long been my practice whether rightly or wrongly—I know I have never done any harm by the practice—in cases of tedious labour in which I have given ergot, or otherwise interfered, to remove the placenta manually after the birth of the child. I have found that the uterus often contracts spasmodically in such cases, and delays greatly the expulsion of the after-birth. It has been my experience that such interference does no harm, and in some cases greatly expedites the termination of the case. This, however, is foreign to the subject, except in this, that on looking at the sex of the child, I have been invariably able, without turning my hand round the uterus, to find the position of the placenta. In cases of female children I have found the placenta to be attached to the left side of the fundus ; when the sex is a male, to be on the right. Over and over again I have found this to be the case. I have listened with the stethescope before birth, and have

ascertained the position of the placenta by the bruit, and have settled in my mind the sex of the child, a fact which has afterwards been verified on its birth. I here give a list of such as I have kept a note of since the fact first struck me as worthy of remark. Several others occurred before I was sufficiently impressed by the continual recurrence of the position of the placenta with regard to the sex of the child, to think them worthy of a place in my memory.

Name.	Posit'n of Placenta.	Presentation.	Mode of Delivery.	Sex.	Observations
Mrs. O'C.	R.	Head	Forceps	M	—
,, —	L.	,,	Natural	F	Ascertained by stethoscope before birth
,, C.	L.	,,	Craniotomy	F	Funis prolapsed, pulseless, passages very small
,, S.	L.	,,	Natural	F	—
,, H.	R.	,,	Forceps	M	—
,, —	L.	,,	Natural	F	Ascertained by stethoscope before birth
,, M.	L.	,,	,,	F	Manual interference for great hæmorrhage
,, M.	R.	,,	Forceps	M	—
,, D.	L.	,,	Natural	F	Three female children, single placenta
,, R.	R.	,,	Forceps	M	—
,, B.	R.	Hd of breech	Natural turning	M	Males (two), single placenta
,, R.	R.	Cross-birth	Turning	M	Boy; dead
,, D.	L.	Head	Craniotomy	F	Hydrocephalic
,, Tr.	R.	Breech	Brought down feet	F	Considerable hæmorrhage
,, Sw.	L.	,,	Born before seen, manually, I believe	F	Born dead

I give the above table for what it is worth, not very much I am aware; were I to lay down dogmatically that the placenta is always attached to the left side of the fundus, or of the uterus, in cases where the child is a female, and as invariably to the right side of that viscus, when the child is a male—I only say that in my experience I have, up this found it to be always the case, and give such instances, that they may turn the attention of others to investigate the matter more closely. It is an old saying, that men endeavour to believe to be right what they think to be right. It seems such an easy solution of the matter that the right ovary should be intended for the production of male and the left for that of female children; it leads me to such a long train of speculation on the causes of a woman having only sons, caused by atrophy or other diseases of the left ovary, or *vice versâ*; it opens up such a field for the stethoscope in determining the sex before birth, and thereby modifying the treatment of cases of contracted pelvis, cases which might be delivered naturally if the child were a female, which would require instrumental interference if it were a male;—that I am to a certain degree prejudiced by the facts I have collected. I hope that the profession may deem my remarks worthy of further investigation, and either refute or confirm them on their merits.

To turn from a subject which is still *sub judice*, I hope I may be allowed to say a few words on a more practical matter; and before I begin the subject I must state that, though I performed the operation in perfect ignorance that any one had done it before me, I disclaim all right to have been the first to do so. A medical gentleman in Passage, co. Cork, performed the operation long before me, as I heard through a mutual acquaintance of ours; I therefore give him all the honour due to priority. I found in some cases where I could not turn, either through the uterus having contracted over the child, or, as happened in one case, from unusual resistance from the soft parts of the mother, I could accomplish the delivery in the following manner:—

I applied steady traction to the arm which, as in those cases, usually protrudes from the vagina, until I had the shoulder down as far as I could bring it; I then allowed the uterus to contract for some short time, I then found that the child was gradually turned, so that the breech presented, and I then easily brought down the feet and completed the delivery. In this I imitiated what usually happens when Nature expels the child by that process usually called "spontaneous expulsion," first accurately described by Dr. Douglas. By traction on the arm, I brought down the shoulder so as to protrude entirely, together with part of the thorax; the uterus then exerts its power on the lower half of the child's body, for as the head is fixed it can have no power on it. To explain: suppose the uterus to exert its power on a body of the shape of the letter U, one leg of which is lower than the other, and immovably fixed; it is plain that the other leg, if the U be a flexible body, must be forced down, and a little power exerted at the angle or head will materially help the action of the uterus, and the movable leg of the U will be expelled.

Thus, by pulling on the arm of the child,you double it, for the head being fixed against the pubis, every effort which extrudes the shoulder makes it more in the shape of a U. The expelling force of the uterus is applied to the legs and buttocks; the latter of which rest on a sliding plane, the sacrum, the buttocks gradually slide down; by applying one's fingers, as is usually done in breech cases, you further assist Nature, and the rest is easily accomplished.

I do not know how the gentleman to whom I have given the honour of priority performs the operation, as I have not the pleasure of knowing him; but, such is the plan I have adopted, and up to this I have found it signally successful.

A CASE OF SEVERE GUNSHOT INJURY OF THE ELBOW-JOINT IN WHICH THE ARTICULATION WAS PRESERVED.

By J. HORNSEY CASSON,

Late Senior Surgeon to Lord Blantyre's Mission to the Turkish Army in Asia.

On the morning of September 10th, last year, when returning home from a slight engagement at the village of Jala, on the plain of Kars, as I passed the camp of the Lesghian Circassians, I was hailed by an orderly of Ghazi Mehemet Pasha, better known as the son and successor of Schamyl, the warrior chief and prophet, to know if I would kindly come and see a wounded Circassian officer. I went into one of the head-quarter tents, and found there a young officer, Mustapha Bey, a cousin and staff officer of the Pasha, who had got a bullet wound *somewhere* in his right elbow-joint. Attending upon him I found a wild looking old Circassian, who was sucking hard at the wound in the vain hope of thus extracting the ball, the safest and simplest method he assured me of performing the operation. After this interesting experiment had been continued for some time, until the operator was thoroughly exhausted with his labours, without, I regret to say, his efforts being crowned with the success they merited, the mollah, or priest, was called into consultation, but by this time the Pasha, who was present, had requested me to interfere. I did so on condition that I should have the officer removed to my ambulance. When he arrived there I put him under chloroform, and then I found that a good deal of sucking and enchantment would have been required to remove the bullet. For some time I could not find it either with finger or probe. There was considerable bulging out laterally of the two condyles of the humerus, and it was evident that some body was impacted in the splnit shaft between them. I enlarged the opening made by the entrance of the

bullet, and extracted a number of pieces of bone, several of them covered with articular cartilage. The ball had fractured the head of the radius as well as the coronoid process of the ulna, and had also carried off a large piece of the external condyle, which was impacted together with the bullet in the hollow shaft of the humerus, and had in its entrance into that cavity, fractured the posterior shell of the bone, forming an obvious protrusion about two inches above the point of the elbow. I made a slight incision over this point through the tendon of the biceps in a line with its fibres, and was thus able to insert my finger and push down the fragment of bone, together with the bullet and a portion of clothing which it had carried before it, within reach of the extracting forceps. The bullet had spread out like a mushroom, and had greatly comminuted the majority of the fragments of fractured bone. The olecranon was fractured, but was retained in position by the tendons and ligaments.

Following what may be considered the invariable rule of military surgery, the proper thing to do would have undoubtedly been to make a complete resection of the joint. I had not the patient's permission, however, to this proceeding, neither had I anything in the shape of a proper splint at hand for the after-treatment of a resection; so I had to content myself with carefully removing all the comminuted fractured bones, washing the cavity well out with carbolised water, inserting a drainage tube, and expecting nothing more favourable than anchylosis, putting up the arm as well as I could at the most useful angle, and in a state of semi-pronation. The wounds I dressed with carbolised glycerine, an application I found most useful in many other cases, and the whole joint I enveloped in marine lint. For a few days there was a great amount of healthy suppuration, which soon abated. After ten or twelve days' rest, I found on examination that there was a certain amount of what seemed *articular* motion, of which the elbow was still capable, and accordingly every two or three days I employed, very carefully and gently, slight passive movement, which each successive time caused less pain. The wounds healed favourably, and in six weeks after the injury I had the satisfaction of assuring myself that there was free movement of the joint, with even a little power of rotation of the forearm; and I have no doubt that the patient, if he has escaped the further perils of the war, is by this time able to use his arm as well as ever. When I parted with him at Kars, at the end of October, he was able to make a few Turkish characters with a pen.

The case seems to me to be of interest as showing that even in very severe injuries of the elbow-joint, movement may be preserved without having recourse to complete resection, and, as I believe in this case, without absorption of the articular cartilage which was left. Some years ago, my old friend, and honoured tutor, Campbell de Morgan, removed the fractured bones from the elbow-joint of a boy at the Middlesex Hospital, without resecting the joint. In this case also the recovery of very complete movements of the articulation was the result.

Clinical Records.

HALIFAX UNION INFIRMARIES.

Short Notes of Cases.

By THOMAS M. DOLAN, L.R.C.P., L.R.C.S. Ed., &c.,
Surgeon to the Infirmaries, Physician to the Halifax Fever Hospital, Yorkshire.

THE wards of a poorhouse infirmary do not afford on an average such an interesting class of cases as those of our voluntary hospitals, but they do open out a wide field for practical work, and for the solution of many of the problems of disease. Though a large number of our patients suffer from chronic diseases, as chronic bronchitis, chronic rheumatism, old-standing liver disease, &c., about which there is little inviting and little new to be written, yet we have also a large number the victims of acute disease in all its forms, and we have oftentimes a most varied selection of obscure and complicated cases, which have drifted into a poorhouse, after passing through the hands of the private practitioner, the club doctor, the infirmary or dispensary surgeon, and the out-door Poor-law medical officer. We are often enabled to furnish the closing details of cases the symptoms of which have puzzled the collective wisdom of the staff of some of our best institutions, and had we the discretionary power we ought to have, of making *post-mortem* examinations, such details might be completed in a more satisfactory manner. Unfortunately, the L. G. B. has not sanctioned our application on this point, though I have no doubt the time will come—and in this I am encouraged by the improvements in modern workhouses—when it will be a matter of astonishment that we had ever to ask for such an essential privilege. It is difficult to understand the grounds of refusal, considering we have so much greater discretionary power over life; but as the L. G. B. has decided, we must only patiently work and wait until some sudden gleam of the importance of the power comes across the official mind. The truest economy of Poor-law medical relief consists in placing the Poor-law medical officer in the full possession of every power, enjoyed by his *confrères* who are attached to voluntary hospitals; in assimilating the management of workhouse infirmaries to the general principle of hospitalism, both as regards suitably constructed buildings and wards, amply ventilated, &c., with baths, lavatories, water-closets conveniently and hygienically situated, &c.; in a word, in contributing all those essentials which are deemed necessary in all voluntary well-organised institutions. It is needless to say, the medical officer should have all medicines supplied to him, and this seems such a fundamental principle that one would almost expect that it would have long since been made a compulsory requirement by the L. G. B. Pauperism and sickness are synonymous, and hence the great importance to society of not only a sufficient staff of Poor-law medical officers, but of a staff placed under the most favourable conditions to arrest, control, and cure disease. If the rates are taxed by the illness of a patient from an acute disease, then the truest economy is to restore that patient to health as soon as possible, for neglect will convert a temporary illness into a chronic one, with a corresponding lengthy drain on the local relief list. Hence it is only fair to expect to have properly remunerated medical officers, with the fullest facilities for the discharge of their duties.

As regards *post-mortem* examinations, it has been urged that poorhouse infirmaries were not designed for the advancement of science or medical knowledge; but as they are intended for the cure of disease, it must follow that everything tending to advance our knowledge of medicine must also help in assisting the primary object for which they exist. On the value of *post-mortems* towards this object there can be no doubt. Those who are familiar with the history of the Poor-law are aware that workhouses are filled with a different class from the one they were meant for; in fact, the word workhouse is a misnomer—they are in the majority of towns, large hospitals, supplementing the General Hospital, and in many towns supplying part of the hospital accommodation. Oppert lays down this rule, a town of 50,000 inhabitants need not have a hospital for more than 150 patients, supposing there is a *Union infirmary for* 50 *beds.*

My experience shows that in some cases the inverse ratio exists. The voluntary hospital consisting of the smaller number, the union of the larger number, of beds; as for instance, the Halifax Infirmary will accommodate 70 patients, the Union Infirmary, 240: actual number on the present date in use (Feb., 1878) 225. So that supposing Oppert's law to be the true one, we have here a violation of it, and not by any means a singular one. Again,

as the infirmary is chiefly devoted to surgical cases, say, at least, 50 of its beds, there cannot be accommodation for the average proportion of medical cases there ought to be in a town like Halifax, of 50,000 inhabitants. This is one anomaly. There is another much more striking. The Infirmary is well and ably officered, it has

1. A House Surgeon.
2. An Assistant House Surgeon.
3. Two Consulting Surgeons.
4. Four Visiting Surgeons.
5. Two Visiting Physicians.

Having an important out-patient department, this staff is not excessive; but in striking contrast with the excellent medical provision made at the infirmary, are my own Infirmaries which have only one medical officer, not even resident. Hence, the patient who accepts the voluntarily aid of the infirmary, has the advantage of select advice from many sources, whilst the poor man, who is often unable to be admitted through want of room, has to seek advice, and admittance to the union infirmaries, where he can only have the medical aid of one, for there is no provision made under the Poor-law code for consultations, excepting in grave emergencies, as the outbreak of an epidemic of fever, &c. So much that has been deemed impossible has become possible, that we may be sanguine enough to look forward to a different organisation in the management of poor house infirmaries.

In paying a "a toll to science," it is easy to see from the following instances how our efforts are hampered by the restrictions imposed upon us. Cerebral localisation is a subject of great interest, and the *post-mortem* room can throw great light upon it. Amongst numerous other patients I have three upon whom I would like to perform an autopsy in case of death, in order to confirm the accuracy of the diagnosis established during life:—

1. Amelia Smith, æt. 45, admitted September, 1874. Paralysis of lower extremities, aphasia.

2. Jane L., æt. 29, admitted 1877. Paralysis of organs of speech only.

3. George S., admitted 1868, from the result of a fall. Imbecility, with a persistent desire to keep walking round in a circle.

It has been said that the elevation of the position of poorhouse medical officers must come from themselves; and in this I perfectly agree, for it must necessarily come to pass, if we discharge the duties of our office with earnestness, zeal, and the same scientific spirit exhibited by our *confréres*, who are attached to voluntary hospitals. We have an equal field, and still more, we are paid for doing work which they discharge voluntarily, though, of course, they look for what has been an injury to our profession—indirect payment. These remarks may not be deemed out of place, as they are solely dictated by my desire to point out some of the anomalies and imperfections of the Poor-law system, with the hope of their being remedied. This can only be done by the freest ventilation, by means of that great power, the medical press, and by our persistently laying before those who have the reins of office, *not our grievances*, but the claims of our patients, and of society.

CASE 1.—*Supposed Case of Fever, with Abscess in Right Groin, really a Case of Strangulated Hernia—Spontaneous sloughing and discharge of Fæcal matter through the Wound—Recovery.*

Giovanni B., an Italian organ boy, æt. 17, was admitted into the Halifax Poorhouse, July 1873; he was supposed to be suffering from typhoid fever; had not been under the care of a medical man. When seen by me, in the afternoon, he was very feverish, tongue dry and furred, pulse hard, wiry, temp. 102—complained of great pain over abdomen. Bowels were confined, and there had been very distressing vomiting. On examining abdomen, I found the cause of all his symptoms in the shape of a seeming abscess in the right groin, which I diagnosed to be strangulated hernia. The parts were swollen, tender, and inflamed, and seemed ready to burst. I returned with my friend, Mr. Hodgson Wright, senior surgeon, Halifax Infirmary, in order to relieve the strangulation by the knife, but it was unnecessary. We found the parts had given way, the contents of the bowel were discharged through the opening, part of the gut protruding in a sloughing condition.

I need not detail all the particulars of subsequent treatment, except he was placed on a most liberal diet, with eggs, brandy, port wine, &c., and Nature, which had done so much towards relieving him, completed her own work, and in six weeks he left the hospital, almost perfectly well. The action of the bowels was established *per vias naturales*.

I had a somewhat similar case in private practice, after an operation for strangulated inguinal hernia, also seen by the above-named surgeon.

CASE 2.—*Ovarian Disease—Dropsy—Discharge of nearly half a gallon of pus—Recovery.*

Wells, Annie, æt. 35, admitted June 1871, suffering from ovarian dropsy; she was in a wretched debilitated condition, and seemed as if she could not live long—her limbs were wasted to an extreme degree, whilst the abdomen was swollen, looking larger by contrast. There seemed but one indication to fulfil, viz., to supply nourishment. She had no pain, or tenderness on pressure for the first fortnight, when some symptoms of tenderness developed, for which I ordered warm applications. About June 25th, there was a small painful point, about half an inch below umbilicus; this gradually became red and inflamed, so that I thought it advisable to puncture it, when some pus flowed out, and on introducing a large trocar, the large quantity of nearly half a gallon of pus was discharged. She was in a very prostrate condition for some time, but rallied, and was discharged in September, 1877, in a condition to resume work, though she still presented signs of the emaciation previously mentioned.

CASE 3.—*Ovarian Tumour—Single Cyst—Tapping—Recovery.*

Emma H., æt. 37, admitted in 1873, suffering from long-standing disease of the eyes; she had also a swelling, about the size of a cricket ball, in the right lumbar region, which sometimes gave her pain, but to which she did not attach much importance. It subsequently become larger and caused her both a considerable degree of pain, and difficulty of moving about, so that she had to be confined to bed. There being evident symptoms of fluid, I tapped it with a large trocar, from which flowed about a pint and a half of thick, ropy, viscid fluid. She recovered speedily. There has been no return of the fluid. She is at present in poorhouse. She was sent for the ophthalmic disease, in 1877, to the Bradford Eye Hospital, where one eyeball was extirpated, the other eye being so far improved by the treatment that she was able to go about by herself.

(To be continued.)

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE last, and annual, meeting of this Society was chiefly occupied with the financial and other business of the Society, the delivery of the President's address, and the presentation of the Marshall Hall Memorial Prize to Dr. John Hughlings-Jackson for his investigations into the pathology of the nervous system.

It appears that the receipts exceeded those of the previous year by about £100; but the year having commenced with a deficiency, instead of the usual balance in hand, the available income was slightly less. The balance in hand was £33 19s. 3d. The total number of Fellows has risen from 651 to 665.

The committee on Membranous Croup and Diphtheria

was still engaged in sifting the material in hand, and their final report would soon be made public. Some change was made with regard to the period of the meetings of the Society, and it was now recommended that the meetings should be held from the fourth Tuesday in October to the second Tuesday in June.

With respect to the library, 443 new works were added last year, and the new catalogue now in progress would probably be in the hands of the Fellows in the course of the year.

The PRESIDENT then called upon Dr. Hughlings-Jackson to come forward to receive the diploma of the Marshall Hall Prize, and addressed him in the following terms:—"Dr. Hughlings-Jackson, I could have wished that, for this night at least, the chair might have been occupied by another than myself, so that you might have received your well-won honour from the hand of one who had himself gathered laurels in the same field as you. But as this cannot be, I have at least the satisfaction of assuring you how much I am your debtor for the light you have thrown on my path in the daily practice of my profession; how often I have found your doubts worth more than many another man's assertions; how, even when I have hesitated to adopt your conclusions, it has been with the feeling that probably you were right and I was wrong—that your keener insight had shown you clearly facts, the outline of which seemed to me still blurred and indistinct. Though all the Fellows acquiesce in the justice of the Council's award, it is yet, perhaps, fitting that I should mention the three chief grounds on which that award was made:—1st. Your contribution to the increase of our knowledge of aphasia, and to the increased certainty of that wonderful discovery by which we are now enabled to localise the power of intelligent articulate speech in a certain district of the brain. 2nd. Your careful clinical observations on epilepsy, and the light you have thereby thrown on many points connected with the structure and functions of the brain. 3rd. Your researches with the ophthalmoscope—that instrument by means of which we see through the eyes, as through windows, to the brain. I hope, in time, we may arrive by its means at something approaching that certainty of diagnosis which auscultation has enabled us to attain in diseases of the chest. In handing to you this diploma, which records your selection as the first Marshall Hall prizeman, I need not urge you to continue your investigations with the same diligence as heretofore, for 'the labour we delight in physics pain;' but do it with the same absence of self-seeking as has characterised your work hitherto, and you will continue to enjoy still the rare good fortune of praise without detraction, of honour without envy."

Dr. HUGHLINGS-JACKSON, in receiving the diploma, briefly replied, thanking the President and the Society for the very high honour conferred upon him, an honour which, above all things, would stimulate him to further exertion.

The result of the ballot for officers and Council for 1878-9 was as follows:—President—Dr. Charles West. Vice-Presidents—Dr. William Wood, Dr. Richard Quain, Mr. Cooper Forster, and Mr. John Wood. Treasurers—Dr. William Wegg and Mr. John Birkett. Secretaries—Dr. James Andrew and Mr. Timothy Holmes. Librarians—Dr. George Johnson and Mr. Savory. Other members of the Council—Drs. Barnes, Begley, Handfield Jones, Octavius Sturges, E. Symes Thompson, Spitta; Messrs. Morrant Baker, H. H. Hayward, Berkeley Hill, and A. B. R. Myers.

Literature.

FERRIER ON THE FUNCTIONS OF THE BRAIN. (a)

THAT great epochs make men and not men the epochs, may be accepted almost as a truism; one of the creations of the present epoch in medicine has been Dr. Ferrier. His book must be considered as marking a great epoch, though it cannot be said to have caused it. The thoughts of scientific men interested in the brain, had begun to concentrate themselves for many years past on the convolutions. The functions of the spinal cord, and of the great central ganglia, or at least one of them, the striatic body, were well known, but that of the convolutions could only be guessed at. While *thought* as a whole was believed to be performed by the grey matter of the convolutions, it began to be suspected that that part of thought comprised under volition and perception might be differentiated in connection with the several organs, to form what have been termed *volitional and sensory centres*, and that all thought in connection with each organ must take place in a special centre assigned to it in the grey matter of the convolutions, and that in these centres the brain *willed* that certain actions should be performed.

Anatomy and pathology were, as is generally the case, the first to indicate this; physiology subsequently demonstrated the truth of the theories formed from a knowledge of anatomical facts. Dr. Hughlings-Jackson gave it a certain basis by his exact clinical and pathological observations, in which he associated certain disorders of motility with lesions situated in the cortex of the hemispheres; not that he was the first or the only one to observe this association, but to him the credit is due of drawing attention prominently to them.

Dr. Broadbent in his wonderfully laborious and elaborate papers on the course of nerve fibres in the brain (which we think have never been sufficiently appreciated, perhaps on account of the extreme difficulty of following them) very distinctly enunciates the theory of localisation of function in the convolutions. In a summary of his previous papers, published in the *Journal of Mental Science*, April, 1870, he wrote as follows: "It is at once obvious that these super-added convolutions will be the convolutions most characteristic of the human brain, and will constitute the difference between one brain and another. The sensations transmitted upwards from the several centres must first impinge upon those parts of the grey matter in which the fibres from the sensory tract or ganglia end; so, again, whenever volitions may be originated, the downward starting point of the motor impulse must be in some convolutions connected by fibres with the motor ganglion or tract. These convolutions, then, which receive central fibres, and are bilaterally associated by the c. callosum, will constitute the perceptive centres of Dr. Bastian, and *centres for the emission of volitional or ideo-motor impulses.* (a) But the perception of sensation and the emission of motor impulses are psychical operations of the simplest character, and are common to man and the lower animals. The higher and more complex operations of combining and compressing perceptions, the formation and elaboration of ideas, are thus almost by way of exclusion assigned to the super-added convolutions; and it can scarcely be considered fanciful to see in the withdrawal of the nerve cells engaged in these intellectual operations from immediate relation with the external world, and in the intricate association of different parts of the surface, conditions adapted to the function attributed to them." If Dr. Broadbent had known, when writing this passage, all the facts subsequently demonstrated by experimental research, he could not have more correctly defined the functions of the cerebral convolutions. These pathological and anatomical facts were supplemented by kindred physiological ones by Fritsch and Hitzig, who proved that the cortex of the brain was susceptible of stimulation by electricity, and, moreover, that centres ruling over the movements of certain groups of muscles existed in the cortex, and could be exactly localised.

Before Ferrier entered into the field of research therefore, the fact of "localisation of function" in the convolutions, was recognised by many, and fairly supported by facts; it was, however, far from being universally or even generally accepted. Ferrier, as it were, took charge of the newly-born fact, and nursed it through its babyhood,

(a) "The Functions of the Brain." By David Ferrier, M.D., F.R.S. London: Smith, Elder and Co., 15 Waterloo Place. 1876.

(a) The italics are our own.

the most dangerous period of its existence, and now by the publication of his book, has turned it adrift as capable of maintaining itself, and the rough world of every day observation must decide whether the young fact is strong enough in truth to live or not.

Dr. Ferrier's work purports, as he expresses it to be, "a systematic exposition of the bearings of my own experiments on the functions of the brain." These had already been brought before the scientific world in various original papers by the author, in the West Riding Reports, the Transactions of the Royal Society, the Philosophical Transactions, and elsewhere. Besides the simple record of the results of his experiments, Dr. Ferrrier has added a general review of the functions of the cerebrum from the standpoint of his own experiments, and has endeavoured to form a physiological basis for the science of psychology.

Even his strongest opponents must admit that Dr. Ferrier has produced a work of which scientific medicine has every reason to be proud. That it is the result of most careful and laborious experimental research, and deep, clear thought, must be the impression conveyed to all his readers. As to the truth of the opinions it advocates, and even of the facts recorded, many will be sceptical probably for years to come; further and widely extended observation can alone decide the question finally. Although the book has been for some time before us, the difficulty of reviewing it has seemed constantly to increase, with the more just appreciation of the importance and magnitude of the subject of which it treats. More time for thought and further observation seemed absolutely necessary before venturing to express any decided opinion upon it. While we feel convinced of the truth of localisation of function in the cortex of the brain, still we feel more and more the necessity of further research on many of the points investigated by Dr. Ferrier, and on others which he has been compelled to leave untouched. We do not propose to consider all the points which present themselves for discussion in connection with cerebral localisations, but rather to confine ourselves to briefly indicating the main outlines of the work, and one or two of the most important questions in relation with it. It commences with a very short—perhaps too short—sketch of the structure of the brain and spinal cord, including the shortest possible allusions to some of the most recent views on the subject. The reflex functions of the spinal cord are next considered by the light of previous and well-known experiments; and in the same manner the functions of the medulla oblongata are passed in review. So far, Dr. Ferrier merely records the work of others, and adds no new facts. It is with the brain itself he has chiefly occupied himself. He now passes on to consider the functions of the cerebellum and corpora quadrigemina; but before doing so, devotes a chapter to the consideration of equilibration and locomotor co-ordination. This chapter is purely theoretical, and though the theory the author propounds is ingenious, still we think he fails to prove it. By this theory locomotor co-ordination is regarded as a reflex act, the result of stimulation of sensory nerves, the most important sensory stimuli producing it being tactile, visual, labyrinthine, and perhaps visceral impressions, acting reflexly, or, as Dr. Ferrier expresses it, by "asthetiko-kinesis" upon a co-ordinating centre in the cerebellum, or corpora quadrigemina, and producing the necessary movements for co-ordination and equilibration. One of the main arguments to which Dr. Ferrier trusts to prove this theory, is founded upon a supposed fact to which we should take the gravest exception, namely, that the want of co-ordination in locomotor ataxy is due to loss or impairment of tactile sensibility; in other words, that impairment or loss of sensation is a necessary accompaniment, or indeed a forerunner, of locomotor ataxy. This is a statement which we do not think is borne out by clinical experience. On the other hand, we should say that it was far more common for loss of sensation to follow, rather than precede, ataxy. It is true that we cannot conceive of ataxy except as motor efforts unrestrained or uncontrolled by sensation. This, however, does not necessarily imply that the sensory nerve cells can no longer receive or recognise sensory impressions. The whole sensory tract may be complete, it is only neccssary that the communication between sensory cells and motor cells should be cut off, the communication through which involuntary reflex acts are produced. These may be destroyed while sensation remains intact; subsequently the disease may invade the sensory cells and centres. Such an hypothesis as this appears to us more consonant with clinical facts, and we think it the one most generally accepted.

The next chapter, devoted to the consideration of functions of the corpora quadrigemina, or optic lobes, is full of interest as a *résumé* of the investigations of others, as well as of those of the author, with regard to the result of destruction and irritation of these bodies. It is certain that they have other functions besides that of receiving retinal impressions, and Longuet is quoted as pointing out the presence of well-developed corpora quadrigemina in animals in whom the eyes and optic tracts are rudimentary. The experiments of the author by means of destructive lesions of the corpora quadragemina, agree in their results with those of Serres, Goltz, Vulpian, and McKendrick, and he shortly sums them up as "producing blindness, paralysis of irido-motor and some oculo-motor reactions, disorders of equilibrium and locomotion, and, in frogs, and, apparently, in other animals, annihilation of certain forms of emotional expression." The optic lobes are said to be especially sensitive to stimuli of all kinds; the results obtained, however, are complex and unsatisfactory; they "are mainly of a reflex nature, and depend on the transference of irritation of sensory to motor centres and tracts." They produce movements of the head, trunk, and extremities, if severe, trismus and opisthotonos, together with dilatation of the iris and vocalisation, the latter, especially, if the testes are excited.

Danileusky has found, and his results have been confirmed by Dr. Lauder Brunton and the author, that "electrical irritation of the interior of the corpora quadrigemina causes a great rise in the blood-pressure, with slowing of the heart and amplification of the pulse waves. The respiratory rhythm is also altered in a marked degree, irritation causing a deep inspiration followed by prolonged and powerful expiratory efforts." Valentin and Budge describe yet another result, namely, a direct influence on the viscera, causing contractions of the stomach, intestines, and bladder. In short, it appears to us that irritation of the optic lobes produces reflex actions of all motor nerves, both voluntary and sympathetic. This probably is the result of their widespread connections with other parts; by their means the eyes are placed *en rapport* with all parts of the body; hence the rapid reflex movements produced by visual impressions.

Dr. Ferrier next passes on to consider that crux of physiologists and physicians—the cerebellum—on the functions of which he throws much light. Flourens long ago stated as the result of his experiments on the organ that it ruled over the co-ordination of muscular movements. Though the results of Weir-Mitchell, Vulpian, Philepaux, and others do not entirely bear out the observations of Flourens, still they all agree that certain disorders of locomotion are induced by injury or disease in this locality. Majendie discovered that division of the middle peduncle caused rotation of the body on its own axis towards the side on which this peduncle had been cut; he also observed certain movements of the eye-ball which corresponded with these movements of rotation of the body. These movements of the eyeball were first observed by Purkinge, in 1827, as occurring in man when a galvanic current was passed through the cerebellar region, and lately were more completely studied by Hitzig in the same manner. The movements of the eyes are accompanied by corresponding sensations of vertigo, in which the external objects appear to move in the opposite direction to that of the eyes. Dr. Ferrier has performed a large number of

experiments on the lower animals to demonstrate both the results of irritation and of destruction of certain portions of the cerebellum; by these, which are in perfect accord with the experiments of others already referred to, he demonstrates that there are certain centres in the cerebellum which maintain the equilibrium of the body, and oppose tendencies to overbalance or fall in certain directions. Thus, irritation of the anterior part of the middle lobe produces backward movement of the head and extension of the trunk and limbs, together with upward movements of the eyes; these movements he regards as counteracting a seeming rotation forward on the horizontal axis—that is, an actual tendency to rotate forwards produces these movements by exciting this centre in the cerebellum, and thus the movement of falling forward is counteracted and arrested; the truth of this is further proved by the results of destruction of the anterior part of the middle lobe, when the tendency to pull forward is no longer counteracted by the action of this centre, and the animal, consequently is constantly falling in this direction. Exactly the reverse of this holds true of the posterior part of this middle lobe, irritation of which produces forward movements of the head and downward direction of the eyes, which antagonise a tendency to fall backwards; after destruction of this centre equilibrium is no longer maintained in this direction, and backward falls result. The centres contained in the lateral lobes are more complex, and the results less certain, it depending on the exact spot injured, whether falling to the same or to the opposite side results.

"Lesions of the cerebellum while interfering with the mechanical adjustments against disturbance of the bodily equilibrium, do not cause paralysis of voluntary motion of the muscles which are concerned in these actions." Dr. Ferrier accepts Vulpian's explanation of the fact that lesions of the one side of the cerebellum are often associated with hemiplegia of the opposite of the body, namely, that "the hemiplegia is not the result of the cerebellum lesion as such, but of compression of the subjacent tracts of the pons and medulla." Lesion of the cerebellum produces a certain amount of derangement of equilibrium on the same side, giving rise to vertigo and unsteady gait; the results of experiment appear to indicate that this can in some measure be overcome or supplemented by the conscious effort of the cerebral hemispheres. The intimate connection of the auditory nerve with the cerebellum through the rectiform bodies, and the remarkable influence of lesions of the semicircular canals upon equilibration, as demonstrated by Flourens, are pointed out by Dr. Ferrier as further proof of the functions of the cerebellum; lesions of the superior semicircular canal corresponding in their results with lesions of the anterior part of the middle lobe of the cerebellum; of the posterior vertical canals with the posterior part of the same lobe; while lesions of the horizontal canals correspond with lesions of the lateral lobe. The intimate connection between certain movements of the eyes and the corresponding centres in the cerebellum have already been referred to; the blindness which so frequently accompanies cerebellar disease is attributed to the impeded return of venous blood from the increased intercranial pressure, leading to choked disc and subsequent atrophy of the optic nerve; this, however, is a purely mechanical result, and has no special relation to cerebellar disease. It is, moreover, suggested as probable that the other special senses, as well as common sensation, are all correlated in the cerebellum with certain motor adjustments connected with equilibration; but on these points no experimental data have been obtained. There are no facts in support of the hypothesis that the cerebellum is the seat of the sexual appetite or rules over the reproductive functions. These results of physiological experiment explain and perfectly agree with the staggering gait and intense vertigo, with a tendency to fall to one side, frequently seen in cases of cerebellar disease.

The author now passes to the consideration of the functions of the cerebrum, and it is with these researches that most of us are now familiar. A chapter is devoted to the explanation of his method of investigation and to its defence; in this he meets the many objections that have been raised to his results, explaining the effect of "extra-polar conduction," and proving conclusively that it is not a cause of fallacy in his observations. It would be out of place here to enter into a discussion of the truth of the theory of cerebral localisation, even if our space would permit us to do so; for ourselves, we firmly believe that, as a principle, it has been established, although as yet but few of the centres can be pointed to as localised, with absolute certainty. The next chapter is devoted to detailing the results of electrical irritation of the various convolutions of the cerebrum in monkeys, dogs, jackals, cats, rabbits, guinea-pigs, rats, pigeons, frogs, and fishes; and also to the results of stimulation of the corpora striata and optic thalami. Throughout the whole series movements on the opposite side of the body could be produced by excitation of the hemispheres; while as low in the series as rats, various movements could be localised to certain areas; all these motor areas being grouped together in a similar manner to that observed in the highest form of animals, namely, on each side of the fissure of Rolando, and in the area occupied by the ascending frontal, ascending parietal and postero-parietal lobule of the human brain, and which is now commonly described as the motor area.

After thus detailing the phenomena produced by electrical irritation of the cortex, Dr. Ferrier remarks that "the mere fact of motion following stimulation of a given area does not necessarily signify a motor region. The movements may be the result of some conscious modification incapable of being expressed in physiological terms, or they may be reflex, or they may be truly motor in the sense of being caused by excitation of a region in direct connection with the motor parts of the crus cerebri. The method of stimulation by itself is incompetent to decide these questions, and requires to be supplemented by localised destructions of those areas, stimulation of which is followed by definite motor manifestations."

The method employed to effect these localised distinctions of brain matter have been chiefly the actual cautery, occasionally excisions. By means of these methods, Dr. Ferrier proceeds to investigate, first the sensory, and afterwards the motor centres. These investigations of the sensory centres we consider by far the most important of any of the investigations detailed in this work, because they are so completely new and original. Many, if not all, of the motor centres had already been established with considerable accuracy by the pathological investigations of Hughlings-Jackson, and the experiments of Hitzig and Fritsch; but previous to these investigations by Dr. Ferrier, no researches of a physiological or pathological nature had in any way indicated the localisation of the special senses. These important results must, therefore, be considered peculiarly his own; they still, however, require the confirmation of pathological observations.

The first centre dealt with is that of sight, which is localised in the angular gyrus (pli courbe), destruction of this convolution producing complete, though only temporary, loss of vision in the opposite eye; if the convolutions on both sides be destroyed, the loss of sight becomes permanent. The movements of the eye produced by electrical irritation of this convolution are thus proved to be reflex in character. It is remarkable that destruction of this centre produces complete loss of vision in the opposite eye, while lesions of chiasma produce hemiopia; this would seem to confirm the recent investigations of Biesiadecki and others, which appear to show that total decussation of the optic nerves takes place in the optic chiasma; but Dr. Ferrier adopts the hypothesis propounded by Charcot, which supposes that those fibres which pass along the outer side of each optic nerve, and do not decussate in the chiasma, decussate afterwards in the corpora quadrigemina, by that means complete decussation of the whole of both nerves is obtained.

Perhaps among the most beautiful of his demonstrations

are those careful observations by means of which the "auditory centre" is localised to the superior in temporo-sphenoidal convolution. In this case, again, reflex movements are induced by its electrical stimulation corresponding to those produced by an excitation of the auditory nerve; the keen appreciation and recognition of the meaning of these movements led the investigator to anticipate loss of hearing as a result of the destruction of this centre.

The "tactile centre" is localised to the hippocampal region, which Dr. Ferrier has taken to include the hippocampus major and uncinate convolution. Although the special centre for tactile sensation has never before been arrived at, yet as the author justly remarks, it has received valuable corroboration from the investigations which have been made, especially in France, localising the production of hemianæsthesia to lesions situated in the posterior part of the internal capsule. The occurrence of hemianæsthesia of cerebral origin was first pointed out, we believe, by Demeaux of Paris, in 1843, by Türck, of Vienna, in 1859; it was confirmed by Jackson in 1866; Vulpian and Charcot prove the same by autopsies; Veyssiere in 1873 proved it experimentally by division of these fibres, and exactly localised it. Picnet, Pitres, Raymond, and Bernhardt have all since quoted cases in support of this exact localisation. Charcot, Landolt, Raymond and others, have pointed out that the nerves of special sense, particularly of sight, are affected together with the hemianæsthesia, if the disease is in the brain, but if in the crura, then the special senses are not affected. But the seat of sensation cannot be in the fibres of the posterior part of the internal capsule themselves; it is evidently in some part above them, to which they are leading, and our author says, that this part is discovered to be the hippocampal region, and nearly the whole of the temporo-sphenoidal lobe, and angular gyrus, for in these parts he finds the several sensory centres; whether these be the exact centres or not, future observations will prove. In the meantime we think that it may be fairly taken as demonstrated, that the grey matter of the convolutions to which the fibres above described lead, *must* be the sensory centres. We have dwelt thus much on this point, because it seems that the whole question of cerebral localisation is involved in it; for if one centre can be localised in the convolutions, why not others?

The centres for taste and smell are localised together in the subiculum cornu ammonis, but it has not been yet possible to differentiate between them. It is pointed out that the sense of smell is lost on the same side as the lesion, and cases of right hemiplegia, with anosmia and aphasia, are referred to, in which the loss of smell was found to occur in the left nostril. Although in the cases of hemianæsthesia previously mentioned, smell is described as diminished on the same side as the loss of sensation, and the opposite to that of the lesion, Dr. Ferrier explains this by quoting Majendie, who found that smell was lost when by reason of division of the sensory branches of the fifth, the sensibility of the nostril was completely abolished.

The results of destruction of the occipital lobes are chiefly negative; the animals upon whom this operation had been performed exhibited, however, a complete loss of appetite for food, although all their bodily functions were performed as naturally as before, and in all other respects they appeared to be in good health. From this and certain anatomical considerations, Dr. Ferrier is inclined to think that these lobes are the seat of visceral sensations. Moreover, on theoretical grounds, and from a consideration of its intimate relations with all the sensations, he suggests that the centre for the sexual appetite might be localised midway between visceral sensations and the centres for the special senses, namely, in the occipito-temporal convolutions.

The localisation of the motor area to the neighbourhood of the fissure of Rolando, as above-mentioned, the experimental proof of which the author now proceeds to detail, is well supported by pathological facts, which are day by day multiplying. Hughlings-Jackson, Charcot, Lepine, Gliky, and many others have contributed, accurately observed, and described cases in support of this; while Nothnagel, Hitzig, Fritsch, Schiff, Hennann, Carville, and Duret have all contributed experimental evidence to the same effect, although they do not all agree in their explanation of the results obtained.

It is a fact remarked by all observers that the motor paralysis resulting from these cortical lesions is almost invariably of a transient character, and, moreover, that the lower the class of animal under observation the more rapidly the paralysis disappears. The law of *suppliance* adopted by Flourens, Longuet, and Vulpian, by which the duties of the centres of one hemisphere are taken up by those of the other, has been demonstrated, we think, beyond doubt to be false, and Dr. Ferrier declines to accept it. That of *functional substitution*, propounded by Carville and Duret, and accepted by Charcot, by which centres of similar function are developed around the one destroyed, is reduced by Dr. Ferrier almost to an absurdity, and satisfactorily disposed of. He would explain the difficulty in another way: he adopts Broadbent's hypothesis of the connection between the motor centres and the compensatory action of the one after lesion of the other, which occurs in the case of all bilaterally associated movements. This theory may be extended to the bilaterally associated cortical centres; but even then it does not account for the more transient nature of the paralysis in dogs than in men. Dr. Ferrier points out, however, the much more automatic character of the movements in the dog than in man, and that they are, therefore, much more under the control of the corpora striata, by means of which alone most of them can be performed; in fact, if we understand him aright, he describes the movements produced after paralysis from cortical lesions, as being automatic and bilaterally associated movements carried out by the corpora striata; a view which seems to us very satisfactorily to overcome the difficulty.

The views of Schiff, Nothnagel, and Hitzig respecting the function of the cortical region, and the result of their destruction or mobility, are briefly enunciated, and we think satisfactorily disposed of; in connection with them, Dr. Ferrier enters deeply into the discussion of the so-called "muscular sense," and of what it really consists; whether as maintained by Brain, Wündt, Weir-Mitchell, and Hughlings-Jackson, there exists a sense of effort in the motor nerves, or the cells from which they take origin, and, in other words, a centrifugal sensation which "coincides with the outgoing stream of nervous energy," as Brain expresses it; or whether, on the other hand, the sensations are centrepetal, and belong to common sensation. To the latter cause Dr. Ferrier attributes it; he regards it as a combination of the sense of effort, associated with involuntary fixation of the chest walls, and of common sensation in the muscles, joints, ligaments, &c. These pages are among the most interesting in the book, but space will not allow us to reproduce his arguments.

Irritation of the posterior part of the middle and inferior frontal convolutions produces movements of the eyes and head which appear to indicate attention, and at this spot Dr. Ferrier anticipates that the power of attention and concentration of thought may be localised; anterior to this the brain affords no experimental evidence of its functions, except that after its removal, monkeys, formerly highly intelligent, become dull and inattentive; in this region it is suggested that the intellectual power is chiefly located, and the imperfect development of the brains of idiots in this region is adduced as an argument in favour of this view.

With regard to the recent writings of Dr. Brown-Séquard against the theory of cross-paralysis and any attempt at cerebral localisation, Dr. Ferrier denies that any of the very large number of cases collected by that writer have been recorded with sufficient accuracy to satisfy the requirements of scientific evidence, and he urges that the whole weight of clinical experience is against these views; although these exceptional cases may even be admitted to number hundreds (a fact by no means

proved), yet the cases confirming the rule of cross-paralysis number thousands. In these remarks we fully agree with the author; indeed we cannot but consider that a study of the recent papers of Dr. Brown-Séquard on this subject affords but a sory contrast to the laboriously minute and accurate observations of other recent writers; observations which have done so much to unravel the entangled web of cerebral physiology. Although it is true all is not yet known, that much still remains to be explained, and that many recent observations mey be erroneous; yet it is not by miserably loose and inaccurate records of questionable facts, that knowledge is to be advanced, or the truth arrived at. If Dr. Brown-Séquard wishes to advance the cause which he advocates, he must give us carefully recorded facts, observed by means of all the aids to accurate observation introduced within the last few years, not loose statements made twenty or thirty years ago, with an utter obliviousness of both macroscopic and microscopic cerebral anatomy.

Passing on now to the basal ganglia, or "ganglia of interruption," the corpora striata and optic thalami, the evidence procurable by experiment is open to many objections, owing to the difficulty of reaching them. Although much discussion still remains as to the functions of the thalami, that of the striate bodies is tolerably evident; they undoubtedly are in connection with the motor tracts of the crura; their irritation causes contraction of the muscles on the opposite side of the body, and their destruction paralysis of the same muscles. Dr. Ferrier believes, and we think his grounds of belief sufficient, that the optic thalami are connected with the fibres of the tegmentum, or sensory tract, and that they are connecetd with the nerves of all the special senses, except the olfactory, and also of common sensation of the opposite side of the body. Cases in which disease of the optic thalamus is found without loss of sensation, are probably due to the lésions not being sufficiently extensive. To explain the affections of motility produced by lesions of the optic thalamus, we must remember the intimate associations between sensory and motor impulses in all reflex and automatic movements are produced chiefly in the spinal cord; the automatic and bilaterally associated movements are chiefly produced by the basal ganglia; movements due to special acts of volition requiring conscious effort are produced by the centre of the cortex. Automatic acts, therefore, which require the mutual co-operation of motor and sensory ganglia, namely, corpora striata and optic thalami, are very liable to be interfered with if this co-operation be prevented by lesion of one or other of these ganglia; thus, in the dog and lower animals, whose movements are chiefly automatic, much paralysis ensues on the destruction of the optic thalamus, while in monkeys or men, whose actions are more frequently the result of volition, the paralysis is not so constant or so severe. The same considerations, as previously pointed out, account for the more permanent nature of lesions of the cortex in man, and the incomplete and very transient paralysis resulting from them in the dog.

It will be well here to enumerate the signs of hemiplegia due to lesions of the cortex, as distinguished from that produced by lesions of the corpus striatum. These are stated by Charcot as follows:—

1. The paralysis is not so extensive, more localised, and more often affects upper instead of lower limbs; it is gradual in its occurrence and not preceded by a fit of apoplexy.
2. The paralysis is incomplete and fleeting.
3. If there is aphasia without paralysis, the lesion is almost certainly cortical; if with paralysis, then certainly central. Occasionally, however, this paralysis may be complete and permanent, and yet due to cortical lesion.

Dr. Ferrier next proceeds to discuss the hemispheres psychologically. He points out that while the sensory centres are the seats of conscious sensation, they are also the "organic register of special sensory experiences," or of the memory of sensations. Thus, if an eye is destroyed, or its nerve divided, sight is lost, but memory of past visual experiences remains; but if the corticle centre for sight is destroyed (*i.e.*, the angular gyrus) the memory of sight is also lost.

In this most interesting and suggestive chapter many valuable suggestions are offered and inferences are drawn from facts, which throw great light on psychology. It is thought probable that each of the various viscera are represented in the cerebral convolutions—probably in the occipital region—and that they may give rise in their varying conditions of health, or the reverse, to feelings either pleasurable or depressing. While the lower animals are in great measure mere "conscious automata," and start in life almost independent of their cortical centres, and require but little education, we must be educated by experience, chiefly of sensory impressions at first, till, in time, we add motor experiences stored in our cortical motor centres, and this opens up the way to new acquisitions termed sensori-motor acquisitions; thus, "our ideas of form are mere revived optical impressions, which are properly limited to colour, but optical impressions, combined with ideal ocular movements"—for example, the sweep of the eyeballs, or the circumduction of the arm and head in following a circle. Speech may be regarded as such a sensori-motor acquisition. In this a cohesion or nexus is formed between two sensory elements, sound and vision, and one motor articulation; intimately combined with these another motor cohesion may be found in writing. The effect of disruption of this cohesion by destruction of one motor element, articulation, is seen in aphasia, when the memory of past motor experiences stored in one convolution—the third left frontal—is lost by destruction of the convolution, just as the memory of sight may be lost by destruction of the angular gyrus. A most excellent description is given of this interesting condition in all its varied forms.

The theory of "inhibition" is well explained, and its great importance and widely extending connections demonstrated. In proportion to its development do actions lose their impulsive character; it "forms the essential factor of attention," and "constitutes the organic basis of all the higher intellectual faculties."

The two concluding chapters of the work are devoted to a diagramatic summary of the preceding investigations, and to a short account of cerebral and cranial topography; the latter affords a concise and lucid account of the cerebral convolutions, and will prove of immense advantage to those readers not previously acquainted with the more recent anatomical descriptions of the convolutions.

After the reception that has been accorded to Dr. Ferrier's work, any praise from us would appear feeble; on the other hand, however, let us caution our readers not to be carried away entirely with the brilliant results and ingenious hypotheses of Dr. Ferrier, giving to them a blind adhesion, without waiting for further facts; these are now fast pouring in, and another year or two will probably enable us to speak much more confidently on many points. Already the functions of the cortex, as a whole, have been in a great measure demonstrated; hemiplegia and hemianæsthesia from cortical lesions must be admitted by most pathologists, but of the localisation of cortical centres for the special senses, we still want further proof. Concerning intellectual functions, we can at present only vaguely generalise, although Dr. Ferrier has gone far towards giving even these generalisations a material basis. Many of our most accurate observers and brilliant intellects are now striving to settle the great question of localisation or non-localisation of function in the brain. We anticipate most valuable results from the method adopted by Prof. Charcot, that of studying cerebral lesions in brains hardened in such a manner that the course and distribution of nerve-fibres can be traced in them; by this method we are sure to obtain many new facts and explain many apparent inconsistencies in cerebral pathology.

Dr. Ferrier has promised a new work on the diseases of the brain, which we await with no little interest; in it we shall doubtless find many observations on the human brain to corroborate his experimental researches on those of animals. In the meantime we would earnestly impress

upon every observer the extreme importance of the utmost accuracy and care in making and recording any observations on cerebral lesions and the symptoms produced by them; indeed, so great a responsibility now attaches to any such records that far better would it be that they should be left undone than be made carelessly, or without a sound knowledge of the anatomy of the brain. Every case now recorded is liable to be quoted as evidence by either party; thus, one man's ignorance may overthrow the results of another's knowledge, and by false evidence an untrue verdict may be obtained.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 13, 1878.

DR. BALLARD'S REPORT ON EFFLUVIUM NUISANCES.

IN the Supplement to the Sixth Annual Report of the Local Government Board, containing the report of the Medical Officer of the Board, we have an interesting series of papers, reports, and memoranda on various subjects connected with the progress of sanitation. In this voluminous Blue-book there are two or three papers on vaccination, vaccine establishments, &c.—an abstract of the medical inspections made in 1876 with regard to the incidence of disease on particular places—papers on hospital hygiene by Mr. Netten Radcliffe—a memorandum on the progress of the Levantine Plague in 1876—and official memoranda on precautions against scarlatina, on local arrangement relating to infectious disease, on re-vaccination, &c. But by far the greater part, and by far the most important feature of this "Supplement," is the long and very able report of Dr. Ballard, on the Effluvium Nuisances which arise in connection with various manufacturing and other branches of industry, and especially with regard to the effect upon health of each such industry, and to the degree in which each nuisance can be prevented. Some idea of the laborious and extensive inquiry which Dr. Ballard has made into this subject may be gathered from the fact that his report, although but the first instalment of the results of his labours, takes up one hundred and seventy pages of the volume before us. It has been, says Dr. Seaton, the great aim of Dr. Ballard to establish his practical conclusions on a sufficient basis of observation, and towards that end no pains have been spared by him to carry out the object he had in view. The present division of his report treats of nuisances arising from the keeping of animals, and from those branches of industry in which animal substances are principally dealt with. It will be followed in due time by other divisions, in which will be fully considered the nuisances arising from branches of industry in which mineral, vegetable, and other substances are chiefly concerned. The task imposed upon Dr. Ballard was no ordinary one, as may be seen by glancing at the list of places visited, the number of institutions and factories examined, as well as from the patient and laborious examinations he made at every place he visited, and from the full and careful description he has given of the results of his inquiries. The report shows that the investigation was conducted with much skill and judgment, and with a mind entirely free from prejudices or preconceived opinions of any kind. He neither exaggerates nor underrates the injurious effects of effluvium nuisances upon the health of those who are exposed to them, and he is very careful not to draw inferences from insufficient data, or imperfect observation.

Few are aware of the highly offensive effluvia which are given off from certain branches of industry. The most offensive are those which arise from refuse animal matters, and the most disgusting of all are the effluvia from the process of gut-scraping and the preparation of sausage skins and catgut, the preparation of artificial manures from "scutch" (the refuse matter of the manufacture of glue), and the melting of some kinds of fat. Manufacturing businesses which deal with vegetable substances only rarely give rise to disgusting effluvia. The most offensive are those in which effluvia are thrown off during the boiling of linseed oil, the manufacture of palmitic acid from cotton oil, foots, or palm oil, and of some kinds of varnish. Among the trades which deal with materials of a mineral nature, the most offensive are those which have to do with the manufacture of ammonium sulphate or chloride, and other processes in which there is a copious evolution of hydrogen sulphide, also those which arise from gas-making, and the distillation of tar. And yet it was difficult to determine exactly to what extent offensive trade effluvia are to be regarded as injurious to health. Dr. Ballard, and his predecessor, Mr. Simon, agreed that any valid statistical investigation into this question was quite impracticable, and that the only method which could be adopted consisted in inquiries addressed to individuals, to members of the profession, and especially to medical officers of health. The question, too, was a very important one; for considering that many of these offensive businesses are great sources of private and even national wealth, and considering that many of them perform a function of some sanitary importance by using up materials that might otherwise be wasted and become a far greater nuisance than the factory which made use of

them; it was very necessary to avoid exaggerating the extent to which these effluvia injured the public health. The term "injurious to health" may mean that some kind of functional disturbance is set up by exposure to the offensive effluvia, and which being repeated, causes an appreciable impairment of the general health; or it may mean that persons so exposed are more deeply and more definitely damaged in health; that their lives are shortened or pursued in chronic ailment, &c. Now with regard to the more slight and functional derangements of health, Dr. Ballard says it is remarkable and instructive how one particular group of symptoms appears to be the most prominent of those resulting from exposure to offensive trade effluvia, and how uniformly this group turns up, whatever difference there may be chemically, in the nature of the particular effluvia. This group consists of loss of appetite, nausea, or vomiting, diarrhœa, headache, giddiness, faintness, and a general sense of depression and *malaise*. And since, continues the writer, these different kinds of effluvia have nothing in common except their offensiveness, it may be inferred that the above symptoms have their origin in the impression they make on the senses. Effluvia, therefore, may be said to be injurious to health, "when, by repetition of the functional disturbances referred to, bodily strength wanes, when habitual lassitude usurps the place of habitual energy, and when, with this, the general feeling of mere enjoyment of living, languishes." But when the point is to prove that even serious disease is occasioned among people who are only living in the neighbourhood of these "offensive businesses," that is to say, by the diluted form in which trades effluvia reach persons outside works, we find that there are many difficulties in the way, and that we have to rely upon very imperfect evidence, and upon *à priori* considerations. A very common argument with manufacturers is that it is impossible to believe that the offensive effluvia from their works can injure the health of persons outside, because their workpeople, who are exposed to them, far more than outsiders, have very good health. Dr. Ballard meets this argument by saying that the workmen are not so healthy as they are represented to be; that many of them do fall ill, or "go upon their club," or seek some other occupation; that, moreover, in the best conducted works special care is taken to protect the men from the effluvia to which they are exposed; and that the workpeople are mostly of the age and sex which offer the greatest resistance to the operations of the ordinary causes of disease. Nevertheless, we are inclined to think that there is more in the manufacturer's argument than Dr. Ballard will allow, and we say this upon the evidence which the writer himself advances in another part of his report with regard to the insalubrity of one of the most offensive businesses he visited. Speaking of gut-scraping and gut-spinning establishments, they are, says Dr. Ballard, the most intolerable of nuisances. "Within the workshops the stench is inconceivably horrible; few persons unaccustomed to it could bear to remain for a single minute in some scraping rooms I have visited, and I myself have had a difficulty to restrain vomiting and to carry on the inquiries I was bent upon. . . . . It spreads from the workshops all round the neighbourhood, and often gives rise to such loud complaints that local authorities in some towns have insisted upon entire removal out of them." And yet so little evidence is there that such putrid animal effluvia injuriously affect the public health, that the several health officers Dr. Ballard questioned on the subject, were unable to furnish him with any evidence either that septic diseases prevailed more in such neighbourhoods than in other districts, or that there was more general sickness, or that zymotic diseases prevailed more, or were more more fatal. This is certainly a very significant fact, especially when we consider that two of the worst establishments of the kind were not situated in the open country, but in the slums of Whitechapel, and in a crowded district of Islington, respectively. It must, however, be admitted that some derangement of the general health must be in many cases a consequence of exposure to these offensive effluvia, although the real cause of such derangement may escape detection. Considering the many other causes of disease that are at work in the neighbourhood of these establishments, it must be very difficult to "gather together a sufficient basis of unquestionable facts and duly to differentiate the influence of concurrent scorbutic conditions." In discussing the question on deductive principles, and reasoning from Mr. Simon's great and truthful axiom of all public and private sanitation, that "filth produces disease," it is obvious that trade effluvia is one element of the atmospheric salubrity of towns, and that trade effluvia of septic origin are unquestionably dangerous, and a fruitful source of disease. There are, moreover, certain spreading diseases the contagium of which may probably be developed under the influence of some kind of effluvia. Erysipelas, and its congener, puerperal fever, is one of these, and some observations induce Dr. Ballard to think that diphtheria may be one of them.

We need scarcely say that various means have been adopted to prevent or minimise these nuisances; and the tendency of the exhaustive inquiry to which we are now drawing attention is towards establishing this point, that all, or nearly all, the trades now so offensive from the diffusion of effluvia may be so carried on as not to cause offence at all, or only offence of such a trifling nature as may well be tolerated by persons who live in communities. As to the different sources of origin of effluvium nuisances, and the general principles of preventing them we must refer the readers to Dr. Ballard's excellent Report; but with regard to the prospects of sanitation in this direction, we may, in conclusion, remark that it is commonly found in practice to be as much to the interest of the manufacturers as of the public that the emanations from offensive processes should be arrested. It is an unquestionable truth that the use of due means to prevent the evils in connection with certain industrial establishments often turns out to be in a variety of ways conducive to the prosperity of the proprietors of these establishments.

THE DENTAL BILL.

THIS measure may, we are glad to observe, be numbered with the unhonoured dead. The House was counted out on the evening when its second reading was set down, and had it not been thus disposed of it would, probably, have been rejected by the House. The Royal College of Surgeons of Edinburgh—one of the bodies named in the

Bill as ready to undertake the licensing of dentists—petitioned Parliament in the following words :—

That your petitioners, having carefully examined and discussed the proposed Dental Bill of 1878, entitled, "A Bill to Amend the Laws relating to Dental Practitioners," are of opinion that certain amendments are necessary to be made on that Bill, which amendments they have on different occasions, and in various communications, submitted to the Dental Reform Committee.

That these amendments are in substance that the title or designation of "Surgeon," used either alone, or in combination with any other word or words, ought to be conferred exclusively on those persons who possess the diploma of surgeon as registrable under the Medical Act of 1858.

That the assumption of such title by any other persons is inconsistent with the terms of the 40th section of that Act.

That it is quite unnecessary and uncalled for, as well as inexpedient and injurious, that such a title should be used or taken by such dentists as are not also at the same time registered as surgeons under the Medical Act.

That your petitioners' reasons for addressing your Honourable House in this wise, on these matters, are—

1st. That the prohibitory clauses of the Medical Act of 1858 seem to have been found inadequate for preventing the use of the word "Surgeon," in the designation assumed by unqualified persons as above adverted to, and that an opportunity now exists for rectifying this deficiency.

2nd. That the general public will be unable to distinguish between dentists who are, and those who are not, surgeons, should the terms of this Bill remain unaltered.

3rd. That the object of elevating dentistry to a higher position, as set forth by the promoters of this Bill, would be frustrated by its enactments here alluded to, since instead of encouraging those practising dentistry to become also surgeons, it would enable them to acquire the title and status of surgeons, through another and subordinate qualification.

That your petitioners have explicity stated these considerations to the Dental Reform Committee, on more than one occasion ; and have urged the interference with the rights, privileges, and interests of duly qualified surgeons, which the present terms of the aforesaid Dental Bill entail. They have also shown that the title of dentist alone, and a certificate of fitness to practise as such, is all that a Dental Bill ought to contemplate, but these suggestions have not been acceded to.

May it therefore please, &c.

(Signed) PATRICK HERON WATSON, M.D.,
Edinburgh, March 1, 1878. President.

It is well that the profession has seen the necessity of speaking out, for, had it treated the subject with as much *nonchalance* as the Medical Council and some of the Colleges have done, its members would assuredly have found themselves ranked side by side with every prescribing druggist in the kingdom, for we learn that on Friday week a deputation from the Chemists' and Druggist' Association waited upon Sir John Lubbock to urge the modification of some of its clauses. The deputation pointed out that it would be a great hardship upon the public, as well as upon the trade, if chemists and druggists were not allowed to practise dentistry. The deputation strongly urged that chemists and druggists should be allowed to extract teeth, &c., adding that in many country districts there were no dentists. Besides, it was urged that chemists and druggists had vested interests which ought to be respected, and that, apart from the discretion of the registrar, it ought to be compulsory for them, if desired, to be registered. In reply, Sir John Lubbock said the object of the Bill was not to interfere with simple operations, which no doubt were very useful and very necessary. The Bill would not prevent operations of the kind mentioned if persons liked to submit themselves, though the practice was to be discouraged. The object of the Bill was to prevent persons holding themselves out as specially qualified dentists when such was not the case. As regarded the term "practising dentistry," he would rather not give a definition. He quite agreed with the deputation that the vested interests of chemists and druggists should be respected, *and he would endeavour to modify the clauses as far as possible, to fall in with the views of chemists and druggists.*

We are sorry to be obliged to remark that the Edinburgh College and most of the journals which represent our profession have contented themselves with defending, what they conceive to be the interests of medical men, and express their willingness that the Bill should pass, if the words which were supposed to interfere with those interests were struck out. We cannot take that ground, nor could we, in the public interest, tolerate a measure which would cause a host of totally ignorant and ludicrously incompetent pretenders to be recognised as legal practitioners in dentistry. We desire to see a registration of dentists, not only of competent and educated dentists, and it is not enough for us that surgeons should be participators in the registration unless it be worthy of their status as gentlemen and men of education.

Notes on Current Topics.

The Army Medical Department.

IT is at least satisfactory to observe that Mr. Gathorne Hardy has awoke to the conviction that the unpopularity of the Army Medical Service is "unsatisfactory." It has taken some years of vehement representations to achieve this result, and it might very likely, have been some years still before it would have been achieved, but for the imminence of war, the ridiculous inadequacy of the medical service of the army, and the bidding of only 19 candidates for the 40 commissions offered to the profession. The *status quo* is vividly described by a military correspondent of one of the daily papers.

"There is no use concealing the fact further that Mr. Hardy is becoming convinced at last that the present system of unification has utterly collapsed, and that to hope for an improvement to manifest itself in the condition of the Army Medical Service under the existing regulations is to hope for a thing which it is out of all reason to expect. The Duke of Cambridge is known to have been for a length of time at variance with Sir William Muir, the Director-General, and other officers of that worthy gentleman's staff, as his Royal Highness is simply disgusted—to use a strong but appropriate term—with the way in which matters have been carried on by the officials in Whitehall Yard. People, therefore, are beginning to ask themselves what the upshot will be of the present difficulty. Medical candidates cannot be obtained to fill vacancies in the department for love or money, as the professors at all the

medical schools make a point of cautioning those under their instruction against allowing themselves to be tempted by the bait offered as an inducement to them to accept service. Sir William Muir and his subordinates certainly have earned a most unenviable reputation for themselves, and I see no hope for them, now that the knell of unification has been so unmistakably struck by the result of the recent entrance examination, following closely as that defeat has done upon the very disgraceful disclosures in connection with the death of the bugle-major of the 3rd Battalion Rifle Brigade at Woolwich. It may be reasonably anticipated that Sir William Muir will tender his resignation, which would, of course, be accepted, and other members of his staff might be expected to follow suit. Then comes the question, who will succeed to the Director-Generalship? Rumour names Surgeon-General C. A. Gordon, M.D., C.B., principal medical officer at Madras, who is admitted on all hands to be by far the ablest man Mr. Hardy has at command, and who is simply idolised in the service. So popular is Dr. Gordon, so straighforward in his dealings, and so professionally capable, that it is a regular fight among medical officers going to India to get posted in his Presidency, where all is contentment and perfect harmony. Dr. Gordon's appointment to Whitehall Yard would be the signal for an entire change of feeling among the members of the medical profession."

The Royal College of Surgeons in Ireland has again addressed a remonstrance to the authorities. It memorial is as follows :—

To the RIGHT HON. GATHORNE HARDY, M.P., *Her Majesty's Secretary of State for War.—*

The Memorial of the President, Vice-President, and Council of the ROYAL COLLEGE OF SURGEONS IN IRELAND,

Humbly Sheweth—That your memorialists, upon the 3rd of June, 1875, officially expressed to Her Majesty's Government their conviction that, unless active steps were taken to amend the condition of the Army Medical Department, "serious public inconvenience would be felt in consequence of there being a deficiency of properly educated surgeons for the service of the army," a state of things which your memorialists regret to learn has come to pass.

Your memorialists beg to state that, in pursuance of charters granted to them by Her Most Gracious Majesty, and Her Royal predecessors, they have "provided a sufficient number of properly educated surgeons for the army;" but your memorialists find that, with hardly an exception, these gentleman will not take service in the medical department as at present organised.

Your memorialists, therefore, feel that they would be deficient in their duty to the Crown, and to the public, were they not to call your attention to these facts, and again urge Her Majesty's Government to take such measures as will tend to restore the army medical service to its former position in professional estimation and public favour.

(Signed), ROBERT MACDONNELL, *President.*
PHILIP CRAMPTON SMYLY, *Vice-President.*
J. STANNUS HUGHES, *Secretary.*

Royal College of Surgeons in Ireland,
Dublin, March 5th, 1878.

Queen's University in Ireland.

OUR notice of the election of examiners last week was in error. Dr. J. W. Moore, Physician to Cork Street Fever Hospital, was chosen examiner in materia medica, not in medical jurisprudence as therein set down. Professor Hodges, of Belfast, is the new examiner in the latter subject.

Pauper Lunatics.

A FEW days ago, a deputation, representing Leeds, Birmingham, and several other large towns, had an interview with Mr. Sclater-Booth to ask the Government to give, with regard to the maintenance of pauper lunatics, the same amount of relief to the unions as was given to county asylums generally. It was represented that so long as payments in the nature of subsidies were made in respect of pauper lunatics in asylums, similar payments in respect to the same class of paupers maintained in special wards of workhouses should be made in proportion to the cost of maintenance. In reply to the deputation, Mr. Sclater-Booth stated that the sum which was voted in 1875-76, estimated to pay a subvention of 4s. a head for lunatics in asylums, amounted to £330,000 per annum; the amount to be found in the Civil Service Estimates for the current year was £385,000, showing an addition of £55,000 in four years. The object they had in restricting the grant to the patients in asylums was that ratepayers, through their guardians, had no control whatever over the expenditure in respect of which the subvention was made. The lunatics were removed to the asylum, and kept at an expense which no pauper could be maintained at in the workhouse. It had been said that the effect of the operation of the grant was to stimulate the removal of imbeciles and chronic cases into asylums which ought to be retained in workhouses. This was probably the case; for the Commissioners had, during the last five years, urged the removal of lunatics from workhouses into asylums, and it had been found out lately that there were many inmates in the pauper lunatic asylums who might fairly and reasonably be retained in the workhouses. It would also be difficult to reduce subvention now paid in aid of the lunatics in asylums, for the weekly charge of them was tending rather to increase than to diminish. Mr. Sclater-Booth drew attention to a remarkable state of things existing in the metropolis. In London there were two large establishments for the treatment of chronic imbecile cases, and although 5,000 such cases were maintained in the asylums, the cost per head was something like 7s. a week. They would at once see what an immense charge would be made upon the rates if it were determined to extend to lunatics in anything but regular asylums the subvention of 4s. In London alone it would amount to £40,000 a year. In the Bill before Parliament dealing with the subject altogether, provision was made for dealing with the difficulty in a reasonable and effective way. It was proposed in the County Boards Bill to provide a machinery by means of which a separate asylum might be constructed for the treatment of such cases in respect of which the charge might be spread over a cluster of unions.

No doubt, as was admitted by Mr. Sclater-Booth, it would be only just to assist those unions which had provided especial accommodation for pauper lunatics. But it is evident that whatever arrangements are made no encouragement must be held out to union authorities to keep in their houses lunatics who are only fit for special asylums. On the other hand, it would be a hardship to the poor patient and his friends if he were to be sent to an asylum far away from his home, when he could be just as well managed, and perhaps be more likely to

recover, within the walls of the union workhouse. Much might be left to the discretion and advice of the medical officer of the union, so that a careful selection might be made of those who were to be sent to asylums, and those who might remain in the workhouse.

Hospitals and the Hospital Saturday Fund.

THE report of the Hospital Saturday Fund, just issued, states that the total amount collected was £5,786 19s. 6d., of which eighteen per cent. was absorbed by necessary expenditure; the sum distributed was larger by £250 than any former year, and the institutions claiming to participate more in number. The Distribution Committee ventures to think the great principle of the movement has been attained, namely, that of enabling those who participate in the advantages of medical charities to contribute something towards their support, and to take an interest in their management. It is further believed by the Committee that if these principles were thoroughly appreciated by the working classes, the £5,000 would, in future years, become £10,000, £20,000, or even £50,000, "a consummation devoutly to be wished." The Committee make some suggestions to hospital authorities, and one or two of which, it is thought may be worthy of consideration; first, the large amount of valuable time that is wasted by the working classes in the waiting-rooms for out-patients, and in their having to go to a particular part of London during the most important hours of the day. This applies more to special than to general hospitals, inasmuch as there are general hospitals now existing in most parts of London, although they are only open (except for accidents and very urgent cases) as a rule in the middle of the day. In some few instances, too, it has been met by special hospitals opening for the relief of patients on one or two evenings a week. This, however, is but a partial remedy, and the committee ask whether it would not be possible for hospitals that are much frequented to open branches in various parts of London. The additional expense would be very slight—no increase in the cost of management would be incurred, by opening at different hours no further staff would be necessary, and for the small rent of a couple of rooms an infinite boon would be conferred upon the working classes. The second point is the desirability of having more homes for the reception of persons recovering from sickness; and thirdly, the desirability of having more convalescent institutions, or homes for the reception of patients recovering from sickness, and which shall receive those living in poor and crowded houses, and requiring further time, rest, fresh air, and good-living, to ensure a good recovery. Awards, we are told, were made to provident dispensaries, because the Committee believes institutions of the kind should be encouraged, but as to "hospitals for the well-to-do," these seem to be scarcely needed; for with a large amount of statistics before the Committee "the multiplication of new hospitals will only lead to large, needless, additional expenditure, already very high, both in management and maintenance."

DR. NICHOLAS WHISTLER COLAHAN has been appointed to the vacant Chair of Materia Medica in the Queen's College, Galway, vacant by the promotion of Dr. Pye to the Chair of Anatomy.

Sanitation at Carlisle.

AT the weekly meeting of the Health Committee of the Carlisle Urban Sanitary Authority, held on the 1st inst, the medical officer reported that during the week 27 deaths have been registered, including two from zymotic diseases, namely, 1 scarlatina in Union Street, and 1 typhoid in Silloth Street. The death-rate is equal to to 42 per 1,000 per annum. In the coresponding week last year there were 18 deaths, including one from whooping-cough, and the death-rate was 28 per 1,000 per annum. The report proceeded to point out that although the death-rate seemed exceedingly large only two were from preventable diseases, and 18 were directly referrable to the remarkable weather we are now and have been experiencing. As it was a year and three-quarters since there was such a death-rate as 42, and as weekly mortality returns were calculated to mislead, he thought it was right to mention the highly gratifying result of sanitary work in Carlisle as a matter of fact and experience. In 1874—the first year of legalised action—our death-rate was 33 per 1,000; in 1875 it was 29 1-5th; in 1876 it was 25; and in 1877 23 per 1,000. There was no reason why they should rest there, as in the course of 22 weeks in the latter half of 1876 our rate was six times as low as 11 per 1,000, and they might try to keep it down to that, and as much below, as an ill-built and perhaps overcrowded town would permit.

At the meeting of the Rural Carlisle Sanitary Authorities, the report was far from satisfactory. The Inspector reported 10 cases of scarlet fever in two houses, which were so dilapidated that some of the sleeping-rooms had no windows. In another house, there had been 5 cases of typhoid fever, which appear to have originated in the bad state of the water used for drinking purposes. Moreover, at a place called Stanwix, the wells appear to be in a very unsatisfactory condition. Nevertheless, the authorities do not seem to make any haste to remedy the evils brought under their notice. The suspected water is only roughly analysed, and the chairman very properly asks, "Is it not a case in which the water ought to be thoroughly analysed?" They also, as in many other places, have a habit of letting things "stand over for a month," and of course while sanitary improvements are conducted in this leisurely manner, more cases of fever break out, and the death-rate is proportionately increased.

Undertaker's Commissions.

A FEW days ago "a medical man" sent to the *Echo* the following letter, which shows the temptation to which some members of the profession are exposed, and to which we are afraid many of them give way:—

DEAR SIR,—In returning the profession my sincere thanks for the liberal patronage and recommendations which I have received from them for the last ten years, I beg respectfully to intimate that, owing to my largely-increasing business, in future, instead of remitting cheques half-yearly as hitherto, they will now be sent regularly every quarter.

Furthermore, in reference to silk hatbands, &c., I have made arrangements, when they are returned in future, to allow the full value of them, and place the same to the credit of the account.

I would also here advise, when favouring me with your

recommendations, that you will as soon after as possible send me your card with name of deceased, so that there may be no mistake made in crediting you with the same. I also deem it necessary, in recommending or sending servants, that you will warn them against making any mistake in the name and address, as there is another establishment within a few doors of me with which I have no connection whatever.

I beg to remain, dear Sir, yours respectfully,
J. W.

We have no reason to doubt the *bonâ fide* nature of this communication, as it is well known that many medical men so far forget themselves as to receive from undertakers a commission or douceur in consideration of their recommendation. Not very long ago a medical friend of ours was offered two or three guineas under the above circumstances, and the undertaker appeared quite surprised when the offer was refused. He went so far as to say that some medical men made "a nice little thing" out of these commissions, but we hope, for the credit of the profession, he was grossly exaggerating the practice of which he was speaking. Nothing, perhaps, should be more revolting to the feelings of a respectable medical man than the idea of making capital out of the death of his patient. And yet we are afraid that there are some who condescend to such mean and mercenary conduct, for such letters as the one we have just quoted could never be circulated were there no practitioners ready to take the bait presented to them.

Diphtheria and Bad Drains.

Dr. Tripe, Medical Officer of Health for Hackney, on Friday reported to the district Board a serious outbreak of diphtheria at Upper Clapton, 12 cases having occurred and 6 deaths, at the Common, Warwick Road, Clarence Road, and Lea-Bridge Road. A personal inspection of the houses in the affected localities by Dr. Tripe showed that in every case but one the overflow pipes to the cisterns were connected with the drains, and the water-pipes also, so that the sewer gas could readily obtain admission into the dwellings. At one large house not fewer than five pipes emptied themselves into the drains without being trapped, so that sewer-gas came up the waste of a fixed wash-basin whenever the plug was taken out.

We have no doubt that, if a thorough house-to-house inspection were made, a similar state of things would be found in a large percentage of the houses visited. This outbreak of diphtheria at Hackney shows the necessity of the medical practitioner making inquiries about the drains whenever he comes across cases of this disease.

The Seamen's Hospital, Greenwich.

Not long ago we drew attention to this valuable hospital, and to the great claim it had upon the charity of the public. We are, therefore, glad to see, from the 57th Annual Report just issued, that the institution is receiving all the support it deserves. The total income last year was £11,653. The average number of beds occupied throughout the year has been much in excess of any previous one. In the past six months nearly 200 beds have been constantly occupied, whereas, the daily average number of beds so engaged during the previous three years was 166. A notable feature in the income of the hospital is the comparatively large amount received from annual subscriptions. These have more than doubled in the last three years, and during 1877 nearly £400 is new annual subscriptions, and £3,000 in donations have been obtained. The local Flower Mission, which has been recently organised by the deputy chairman, has been a great success. The patients take a real interest in the work, and become much attached to the flowers, which they carefully husband throughout the week until a fresh supply is forthcoming. That a few pictures in the wards of our different hospitals would be a great acquisition has long been felt, and, as regards the Seamen's Hospital, upwards of 100 framed pictures have been received in response to a letter on the subject, which a few months ago the chairman publishad in the newspapers.

We need scarcely say that we hope this Institution will go on and prosper, for on no class of patients, should the charity of the public be more generously bestowed than upon our seamen, whose life, as Mr. Thomas Brassey, M.P., remarked, is at best but one of "danger, privation, and hardship."

Dr. Seaton on Re-Vaccination.

We have always attached much importance to re-vaccination, and therefore we are glad to see there is a memorandum on the subject in the recently issued Report of the medical officer of the Local Government Board. Generally speaking, remarks Dr. Seaton, the best time of life for re-vaccination is about the time when growth is completing itself, say from fifteen to eighteen years of age, and persons in that period of life ought not to delay their re-vaccination till times when there shall be a special alarm of small-pox.

We are strongly of opinion that there would be a great deal more re-vaccination if the family medical man always made a point of drawing the attention of parents to the necessity of their adult children being re-vaccinated. We feel certain that, as a rule, medical men neglect to do this, little thinking how, by insisting upon the repetition of the operation, they have it in their power to starve, and, therefore, to weaken the force of any future epidemic of small-pox. It is not generally known that provisions for re-vaccination are made in the 8th sec. of the Vaccination Act, 1867, &c. Under these provisions re-vaccination is now performed by all public vaccinators, and, so far as is not inconsistent with the more imperative claims for primary vaccination, any person coming within the terms of those provisions may, on applying to the public station of his district, obtain re-vaccination free of personal cost.

A New Marking-Ink.

There are few inventions, or improvements on inventions that are so acceptable to the general public as those which supply a domestic want. This marking-ink, or *Mather's Nigrine* as it is called, appears to us superior to any other kind of marking-ink. One great advantage it has over all others is that no preparation or heating is required after writing with it. It can, moreover, be used with any kind of pen; it becomes blacker with repeated washing; and it cannot be removed by any chemical means. Neither acids nor alkalies will efface the impression of this ink, which will even stand boiling in solutions of cyanide of potassium, caustic potash, bleaching

powder, and other destructive agents. We have no doubt a good deal of chemical skill and ingenuity have been exercised in the manufacture of this simple article, and we feel sure that there is not a household which will not experience the advantage of using it in preference to any other kind of marking ink.

Small-pox and Vaccination Prosecutions.

Last Friday Earl Percy asked the President of the Local Government Board whether it was a fact that, according to some statistics he quoted, small-pox had been much on the increase since 1862, and, if so, to what he attributed the increase in this source of mortality, and whether he contemplated taking any fresh steps to arrest it. To this Mr. Sclater-Booth replied that the increase in the mortality from 1867 to 1876 was due entirely to the epidemic which broke out in 1871, and lasted to 1872; for the remainder of the eight years the mortality was below the average.

Mr. Hopwood then put the question "whether the President of the Local Government Board was aware that Charles W. Nye, of Chatham, had been prosecuted eight times for not having his children vaccinated, and whether, in view of this and other like cases, the Government would support the Bill of the hon. member for South Durham, or propose some other remedy." Mr. Sclater-Booth denied that two of this man's children had died from vaccination, as was alleged, and he said that no alteration of the law was necessary, provided the local authorities would use reasonable discretion.

We have more than once given our opinion respecting these petty prosecutions of the opponents of vaccination, and all we have to say now is that it is to be regretted that this question of vaccination prosecutions should be so often cropping up instead of being finally settled. For, as the law stands, either, through the "reasonable discretion" of "the authorities," the irrepressible anti-vaccinator will gain his point, and defy the law, or the authorities must persist in a species of petty persecution which seems to be neither dignified nor successful.

The Surgical Aid Society.

We have more than once had occasion to direct attention to the questionable charity of the Surgical Aid Society, and to the manifest inconsistency of compelling maimed and crippled invalids to submit to a wasting and fatiguing canvass for letters. A case in point came before the city magistrates last week, which peculiarly illustrates the indefensible system pursued by the Society.

Sir Robert Carden having made some severe remarks on the Surgical Aid Society (after a complaint made by Jacob Smith, who lost a leg in the Indian Mutiny) the treasurer and secretary attended at Guildhall to offer an explanation. They stated that when Smith applied for a limb they decided that he should have one; but after a "long correspondence with the Charity Organisation Society," that body reported that he was an impostor. Sir Robert Carden said that the man's statement was that he applied to the Surgical Aid Society for an artificial leg, and that he had a great deal of trouble to get the required number of letters to get it, and that he had to come up to London to get it repaired. That the Society told him that he must get ten more letters before he could have his leg returned to him, and that when he got those letters his leg would be sent to Dover to him, and that he wanted money to carry him back to Dover. The magistrate strongly condemned this system of compelling poor people to get a number of letters, as many as forty being sometimes required, and said he could not understand the benefit of such a society.

The Medical Society of London.

The one-hundred-and-fifth anniversary of the Medical Society of London, was celebrated on Friday evening last, at the Grosvenor Gallery Restaurant. The chair was occupied by the President, Dr. George Buchanan, who was supported on his right by the President of the College of Physicians, Dr. Risdon Bennett, on his left by the President Elect, Professor Erasmus Wilson, F.R.S., and by a very large muster of the Fellows of the Society. The various toasts of the evening were interspersed by some excellent singing, contributed by Dr. L. S. Forbes Winslow, Dr. E. A. Semple, Dr. Cooper Key, and other members of the Society. Dr. Bennett responded in elegant terms for the Medical Corporations, and Mr. John Gay for the College of Surgeons. The evening passed off pleasantly enough, with the exception that the ventilation of the room was felt to be anything but agreeable.

Charing Cross Hospital.

Considerable dissatisfaction has been expressed on the part of some of the Governors of this hospital on account of the action taken at the general meeting by certain members of the body, who on personal grounds alone, carried, by a small majority, a resolution to extend the term of office of the senior surgeon. The gentleman in question has already enjoyed an additional period of five years beyond that contemplated by the rules of the hospital, to the disparagement of the junior members of the staff, who have a right to expect promotion.

Arrangements are being made at Paris for the erection of a fitting monument to the late Claude Bernard. The initiative has been made by the *Société de Biologie*, of which Bernard was one of the founders, and over the meetings of which he has presided during the past eleven years. The committee appointed for the purpose contains prominent names from all the leading scientific institutions of Paris.

The Borth fasting girl was on Wednesday, accompanied by her aunt, removed from Borth into the infirmary at Aberyswith, at which institution she is attended by Drs. Roberts, Gilbertstan, Jones, and T. Harris. Since she has been confined to her bed, and has, according to what is alleged by her relatives, eaten nothing, she has not only grown out of the clothes she used to wear, but actually increased in weight. On Thursday, however, the medical men in charge of the case very properly administered to the "fasting girl" a quantity of milk by force.

Ruhmkorff, who recently died in Paris, at the age of 74, was a native of Hanover, and in 1844 brought out his first invention, a thermo-electric battery. In 1850 he pro-

duced the splendi instrument with which his name is connected, called the Ruhmkorff Coil, and which at once acquired European fame. For this invention he was rewarded by a medal and decoration at the Exposition of 1857, and in 1858 h · eceived the prize of 50,000 francs (£2,000) at the French Exhibition of Electrical Apparatus.

THE Marshall Hall Quinquennial Memorial Prize, which was founded for the encouragement of researches into the pathology and physiology of the nervous system, has been awarded by the Council of the Royal Medico-Chirurgical Society to Dr. Hughlings Jackson, than whom few have done more honest and laborious work in this department of medicine, and whom we heartily congratulate upon the honour.

ST. PETERSBURGH still enjoys the unenviable reputation of being the most unhealthy city in the world. The last official weekly return gives the death-rate of this city at 57 per 1,000 of the population, the corresponding rate in London and New York being considerably less than one-half, namely, 24 per 1,000. Even the notably unhealthy cities, Calcutta, Turin, Naples, Alexandria, Bombay, are a long way below St. Petersburgh with a death-rate of 36, 38, 39, 40 and 41, respectively.

THE mortality last week in the four principal cities of the United Kingdom was in London 24, Glasgow 24, Edinburgh 27, Dublin 33 per 1,000 of the population. Of the large towns in the second category, Portsmouth stood lowest with 16, and Norwich, Brighton, Plymouth, and Liverpool highest with 30 deaths per 1,000 of the population.

WHOOPING-COUGH and small-pox continue to be the most fatal diseases in London at present. Of the former 112 died last week, and of the latter 54, being the highest number in any week but one since June last. During the last six weeks 267 fatal cases of small-pox were registered in London, whereas but one occurred in the whole of England in the same period.

THE Fothergillian Gold Medal of the Medical Society of London for 1878, has been awarded to Dr. J. Milner Fothergill. The subject was "The Antagonism of Therapeutic Agents." The Silver Medal for the best paper read before the Society, during the last session, was awarded to Dr. Julius Althaus for a paper on "Disease of the Anterior Cornua of the Cord."

THE first of the Gulstonian Lectures at the Royal College of Physicians of London will be delivered on Friday next, at 5 o'clock, by Dr. Ferrier, who will conclude the course on Wednesday and Friday in next week, at the same hour and place. The subject chosen is "The Localisation of Cerebral Disease."

A PUBLIC meeting on behalf of the Building Fund of the North-Eastern Hospital for Children was held at the Mansion House, yesterday (Tuesday), by permission of the Lord Mayor, in aid of the Building Fund for a new wing to contain 50 beds, on the freehold site in Hackney Road.

MR JUSTICE DENMAN has presented the sum of £900 to the University College Hospital, Gower Street, being his share, less expenses, of the amount realised by the sale of Serjeant's Inn.

Correspondence.

GUMMI RUBRUM IN THE TREATMENT OF DIARRHŒA, DYSENTERY, ETC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having read in "Squire's Companion to the British Pharmacopœia" of the therapeutic effects of the gummi rubrum, and being in a district where diarrhœa and dysentery are very prevalent, I was led to try it in cases where other remedies had failed, and from the general success attending its use, I have adopted it in all severe cases, after inflammatory symptoms had subsided. I have this Spring used it in twenty-seven severe cases with the most satisfactory results, in the following manner—

℞ Pulv. gummi rubrum, gr. ij.
Aq. ad ʒj.

Mix thoroughly, take three times a day in port wine ʒss., the wine covering the bitterness of the mixture.

Trusting that the foregoing may assist in bringing into notice a valuable remedial agent which seems to be but little known, I have the honour to remain, Sir,

Yours faithfully,
T. M. SHERIDAN.

Charley's Creek, Queensland.

Medical News.

University of Dublin.—At a meeting of the Senate, held on March 5, the following degress were conferred :—

BACHELOR IN SURGERY.—Ulysses Arthur Daly, Thomas Frederick Fogarty, Clemens Mallins, Edward William Wood White, Alexander George Young.

BACHELOR IN MEDICINE.—Henry Lawrence Cox, Edward James Cowen, Constantine Richard Egan, Ulysses Arthur Daly, James Dunn Day, Abraham Cowley Malley, James Acheson M'Cullagh, William Cox Neville, Alexander Pentland, William Craven Rockliffe, Charles H. Tench, Alexander George Young.

MASTER IN SURGERY.—Cedric Herbert Hurford, Rogers Wetherall Gore Taylor.

DOCTOR IN MEDICINE.—Jas. Alexander, Ephraim M'Dowell Cosgrave, George Gibson, John Arthur Irwin, William Craven Rockliffe.

Presentation to Dr. Muter.—On Wednesday, the 6th March, the present major and minor students of the South London School of Pharmacy, met their respected director, Dr. Muter, at the conclusion of the chemical lecture, and presented him with an address expressing their respect for him as a teacher, and their warm feeling towards him personally. The address was accompanied with the gift of a magnificent silver and crystal epergne, most tastefully loaded with fruit and flowers. The presentation was to have been made on the doctor's birthday (27th February), but owing to a delay in the production of the inscription, &c., it had to be deferred. Dr. Muter who was much moved, replied in a few feeling words, and the proceedings terminated with hearty cheers again and again, as he retired, almost bending under the weight of the splendid present.

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.—Subscribers who have not already paid their subscriptions are reminded that they are now due, and should be sent to the publishers, who will be happy to acknowledge their receipt. Subscribers who pay in advance will oblige by remitting, at the reduced rate of One Guinea, during the present month.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MEDICAL WITNESSES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—You will much oblige me by answering the following question in the next issue of your influential journal,—viz. :—

I am attending a man who has been assaulted, and he summoned me as a medical witness to the Petty Sessions' court. Am I bound to attend without a fee, or, if I do, am I bound to give evidence without one?

I enclose my card, and remain,

Sir, your obedient servant,

J. A.

[The law as to medical witnesses is undecided. If the case be a criminal prosecution you must attend if served with subpœna, and your only remedy will be to appeal to the court and object to be sworn as to matters of professional opinion. As to matters of fact you must testify as any other witness would be obliged to do. If the case be a civil action the subpœna has not the same force, but if you disregard it you are theoretically liable to an action in case it is shown that the case was lost for want of your evidence. It is generally quite impossible to prove this.—ED. M. P. & C.]

MRS. VICTORIA C. WOODHULL.—Our contemporary, the *Philadelphia Medical Times* notices "that the notorious Mrs. V. C. Woodhull, who is now starring London and other large cities, has a very appreciative hearer in the London *Medical Examiner*. The theme of her lectures appears to be a congenial one, namely, 'Procreation.'" Our Philadelphia contemporary "trusts that she will meet with a measure of success which shall induce her to *tarry* among our British cousins." We hope our American contemporary does not take the paper quoted as representing in any way the profession of these Isles. But one other medical journal noticed Mrs. Woodhull's lectures at all, and that to condemn.

MILITIA ARMY MEDICAL DEPARTMENT.—We observe from the Official Army List that Surgeon-Major R. J. Magee, of the Kilkenny Fusiliers, having completed 20 years full pay service entitles this officer to the relative rank of Lieutenant-Colonel, in accordance with the Royal Warrant of 1876.

THE "ECHO" AND THE MEDICAL STUDENTS.—Dr. W. T. Greene, referring to our strictures of the *Echo* on the above subject, thinks that the profession can afford to ignore the slanders of the costermonger's halfpenny organ, which are, in his opinion, best met by silent contempt; for recognition, even in reproof, by a respectable journal only seems to encourage the *sans culottes* of the daily press to further efforts of scurrilous invective against the profession.

SPINAL CURVATURE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your review of my work on "Spinal Curvatures," in your number for December 19th, 1877, the following passage does me an injustice:—

"We presume that Sayre was unaware of Dr. B.'s existence, but we think it right to mention that Dr. Bryan was house-surgeon in Bellevue Hospital, the Institution with which Dr. Sayre is prominently connected in New York."

At the time of Dr. Bryan's experiments I *was not* connected with the Hospital.

My book was sent to the press in December, 1875, and published in January, 1876, some *three months* or *more* before I ever heard of Dr. Bryan's name in connection with the matter, and of course I cannot be blamed for not referring to him in *it*.

Respectfully, your obedient servant,

285 Fifth Avenue, New York, Feb. 20th, 1878. LOUIS A. SAYRE.

MR. HAY.—You appear to have brought your investigations to a very satisfactory point. We will report later on.

WOMEN DOCTORS.—Our correspondent's letter on this subject is not written in a style which will add weight to the argument. We regret, therefore, to be obliged to decline it.

Mr. G. B.—The subject is treated in a very exhaustive manner in the *Veterinary Journal*.

MR. WATSON would probably get the information from the Secretary of the Society in question.

COMMUNICATIONS, Enclosures, &c., have been received from—Sir Michael Hicks Beach, Bart., Colonial Office. Mr. Haynes Walton, London. Mr. Rivington, London. Mr. Drake, London. Dr. Moore, Dublin. VACANCIES.

Dartford Union.—Medical Officer to the Workhouse. Salary, £85, with the usual extras. Applications before the 16th inst. to J. Hayward, Esq., Dartford, Kent.

Dunfanaghy Union, Falcaragh Dispensary.—Medical Officer. Salary £100. Election, March 22.

Lincoln General Dispensary.—Medical Officer. Salary, £150, with furnished apartments, &c. Applications to the Secretary before the 16th inst.

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150, with board, &c. Resident Medical Officer. Salary, £250, with board, &c. Resident Medical Officer for the Fever Hospital—Salary, £200, with board. &c. Resident Medical Officer to the Convalescent Hospital—Salary, £150, with board. Applicants must address the Chairman of the Board for either post, accompanied with testimonials, &c., on or before March 31.

Sligo Union, Carney Dispensary—Medical Officer. Salary, £120. Election, March 13.

West Sussex Infirmary, Chichester.—House Surgeon. Salary, £80, with board, &c. An additional £20 is allowed for the duties of Secretary. Applications to the Secretary before March 30.

Worksop Dispensary, Notts.—Resident Surgeon. Salary, £220, with furnished apartments, &c. Applications to the Chairman of Committee by the 22nd inst.

APPOINTMENTS.

BARLOW, W. H., M.D., Consulting Physician to the General Hospital and Dispensary for Sick Children, Manchester.

BROWN, G., M.R.C.S.E., L.S.A., Honorary Surgeon to the Booksellers Provident Institution.

COLAHAN, N. W., M.D., M.Ch., Q.U.I., Professor of Materia Medica, Queen's College, Galway.

GIPPS, A. G. P., M.R.C.S.E., a Junior Resident Medical Officer to the Royal Free Hospital.

GREENWOOD, M., M.R.C.S., House Physician to the London Hospital.

HOWITT, T., F.R.C.S.E., Honorary Consulting Surgeon to the Lancaster Infirmary and Dispensary.

HUGHES, J., F.R.C.S.E., Medical Officer to the Police Force, Carmarthen.

KENNEDY, H., L.R.C.S.I., Lecturer on Anatomy at the Ledwich School of Anatomy, Medicine, and Surgery, Dublin.

MCJANNET, F. M., M.B., C.M., Medical Officer of Health for the Parish of Campsie, Stirlingshire.

MCNULTY, J., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Killala Dispensary, Killala Union.

PHILPOT, J. H., M.D., M.R.C.S.E., an Attending Medical Officer to the Royal Pimlico Dispensary.

PICK, T. P., F.R.C.S.E., a Surgeon to St. George's Hospital.

STIRLING, E. C., M.B., F.R.C.S.E., an Assistant Surgeon to St. George's Hospital.

Deaths.

CAMERON.—On March 1, at West Kilbride, James Cameron, L.R.C.S.Ed., of Methven.

CORBETT.—On March 6, at 8 Lansdowne Road, Dublin, J. Henry Corbett, M.D., late Professor and Examiner in the Queen's University.

CRICHTON.—On March 3, at Sonachan, Lochawe, Argyllshire, N.B., Charles Crichton, Surgeon, aged 78.

CURRAN.—On March 3, at Mansfield, Notts, J. W. Curran, L.K.Q.C.P.

EVEREST.—On Feb. 28, at Rainham, Kent, of pleurisy, William Bentham Everest, M.R.C.S.E., aged 84.

JOHNSTON.—On March 3, at Bangor, co. Down, Henry M. Johnston, L.R.C.S.I., formerly of Belfast, aged about 50.

RIMINGTON.—On Feb. 21, at Hastings, William Ballantine Rimington, Surgeon, aged 68.

SMITH.—On Feb. 22, at Kinderton, Cheshire, Thomas Bower Smith, M.R.C.S.E., aged 41.

IRISH POOR-LAW INTELLIGENCE.

LIMERICK.

OPEN STREET DRAINS.

Mr. Corbett read a letter from the Local Government Board acknowledging the receipt of the minutes of the previous meeting, containing a notice of motion for that day fortnight in the following terms:—"That where surface drains are, and can be made, available for sewerage purposes, the utilising of these by the owners of house property, will meet the requirements of the sanitary committee," and in reference thereto, the Local Government Board think it right to observe that the use of open channels for conveying sewage matter in the ordinary meaning of that term, cannot be practised with safety, and that, notwithstanding any implied section, such as contained in the notice, any person using open channels for the purpose of conveying sewage matter would still be liable for the consequence of creating, continuing, and maintaining a nuisance.

Mr. Bernal said that Mr. Cronin's notice was purely opposed to law.

SEWERAGE OF THE IRISHTOWN DISTRICT.

Dr. Barry (consulting sanitary officer) submitted a report, which contained the following:—

With regard to surface drainage for sewerage purposes, I would altogether exclude it from my recommendation. If, by surface drainage it is meant to be conveyed that the channel courses of our streets are to be made the receptacles for the most intolerable nuisance, then I cannot conceive any more retrograde movement in sanitation. I would submit one or two recommendations which I consider necessary to the sanitary condition of this district. As it appears there are 100 houses in this district without pipe-water, steps be taken to encourage or compel its introduction. That, as there are about 15 privies in 96 houses having yards, attention be at once directed to their serious deficiency.

KILDYSART UNION.

RED TICKETS.

Dr. Blackall, adverting to a red ticket which he received, said that any one having land or trade is bound to pay a fee, and wanted to know whether the patient was a man entitled to relief or not.

Mr. Hennessy—Although this man has land, he is very poor.

Dr. Blackall—He is possessed of some land, and has a son a good tradesman.

Chairman—It is perfectly right that a ticket should be cancelled if it is right to do so, and Mr. McMahon tells you that he has a lease of his land, and that disqualifies him.

Mr. Cannon (to the issuer of the ticket)—You should know the people in your district who wants relief, and if you issue a red ticket you ought to state that he is a poor man, but illegally entitled to get a red ticket.

Dr. Blackall said that as far as he knew there was no exact definition for those who are to get relief; but people who have lands, trades, &c., are exempt from getting relief.

WATERFORD GUARDIANS.

The Kilmackevogue Dispensary committee reported that a meeting of the committee had been held, at which they resolved to direct the relieving officer to provide a temporary medical officer, at three guineas a week, to perform the duties of Dr. Cane, who was unwell.

A letter was read from the relieving officer, stating that, in compliance with the order of the committee, he had called upon several medical gentlemen in the city, all of whom refused to act upon the terms, except Dr. Cutlar, who consented on condition of receiving £1 additional for car hire.

It was decided that the report of the committee be adopted, Dr. Cutlar to be appointed without any remuneration for car hire.

LIMERICK UNION.

Alderman Myles, Hon. Sec., read a letter from Dr. Carey, one of the dispensary medical officers, in which he wrote: "I regret to say I am very ill and sick, and I enclose a certificate from Dr. Delander. I would recommend Dr. Malone as my substitute, but don't know if he will act. That's a matter you must arrange yourselves. Of course I have no objection to any other doctor whom you may appoint." Dr. Delander's certificate was to the effect that Dr. Carey was confined to bed with extreme debility. He believed he could not discharge his duties as medical officer without danger to his life. He found Dr. Malone in charge of the dispensary, who informed him that he attended that day to oblige Dr. Carey, but that his own practice would not permit him to discharge the duties, and that he could not attend any more. He (Alderman Myles) then appointed his own son at three guineas per week, until the next meeting of the Committee. It was now for them to confirm his action.

Mr. Lenihan—I thought it was our duty to appoint a substitute during the illness of Dr. Carey, and that that duty lay in the hands of the Committee.

Mr. Cronin—That was my impression too.

Mr. Lenihan—I did not think the appointment lay with an individual.

Chairman—The appointment has not been made at all yet.

Alderman Myles—I was placed in an emergency, and if I had not appointed my own son the business could not have been done.

Chairman—We are indebted to Alderman Myles for his prompt action in the matter.

Mr. R. McDonnell had no doubt the arrangements made by Alderman Myles would be sanctioned by the Committee. He believed he was speaking the feelings of every one present in saying that they all regretted the circumstances under which they were met. Dr. Carey was an old and respected friend who was well known to them all for many years. His services to the institution in which they were assembled could not be over rated. He knew himself from long experience and from his conversations with poor men, how kind, gentle, and forbearing he had always been in his treatment of the poor.

Mr. Gaffey proposed that Dr. Meehan, if appointed, be paid at the rate of £100 a year.

Alderman Myles—I beg to resign the office of hon. secretary, and request that you will appoint somebody else.

Chairman—I am sorry to hear our hon. secretary make such an announcement.

Mr. Lenihan—I don't suppose that anything I could say would induce Alderman Myles to alter his determination, but I must say independent of any consideration, that if we lose his services as our acting secretary, we will lose the spirit and the right arm of this business.

Alderman Myles—I never knew before that when a hon. secretary stepped in in a case of emergency, and when he acted according to the best of his judgment, that a slur would be cast upon him. I won't throw away my labour on people who don't appreciate it.

Alderman Synan—We all appreciate what you have done.

Alderman Myles—Thank you for nothing. I won't give my services for nothing any more.

Dr. O'Sullivan—I had a conversation with Alderman Myles to-day, and I believe that, independent of what has occurred to-day, he would not retain the office.

Alderman Myles—My son would not be a candidate for the permanent office of dispensary doctor, for his practice would not allow him. He would not look for such a beggarly appointment.

Dr. O'Sullivan—I wish to God I had a beggarly appointment now.

Alderman Myles—If I knew what was to take place I would not have taken the trouble that I did.

Rev. Archdeacon Hare proposed that the unanimous thanks of the meeting be tendered to Alderman Myles for his past services, and that they should express their deep regret that he had seen fit to resign. Passed.

THE SANITARY STATE OF NAAS.

THE following letter from Dr. J. Smyth was read :—

"GENTLEMEN,—I beg to report to you the disgraceful state of many of the lanes and some of the outlets of the town of Naas. They are almost habitually polluted by nuisances of the most disgusting kind. As an instance, I would particularly mention the lane leading from Poplar Square to the Sallins Road, through which a large portion of the Catholic congregation pass on their way to and from the church.

"I have also to report to you the neglected condition of the locality known as the Fair Green, which at times is almost impassable. The only attention I ever see shown to it is by the residents of the adjoining houses, who gather the filth into heaps, and after some time remove it to the rear of their wretched dwellings, where it remains poisoning the atmosphere for months until disposed of. This can hardly be called a legitimate industry.

"The next matter I have to submit to your consideration is the existence of a structure in the very centre of the leading thoroughfare of the town, the outside of which is used, especially on fair and market days, as a public urinal. Twelve months ago I represented the nature of the evil to the commissioners, without, however, any good result. The unsightly building remains, and is still the occasion of nuisances, moral and material, which are an outrage on decency and an injury to the public health.

"Lastly, I have to complain of the custom which prevails in many portions of the town of making the street the receptacle for slops which are more nasty than nice, together with house refuse of all kinds. I would recommend the sanitary board to publish notices strictly prohibiting this very objectionable practice, and warning offenders that the penalties of the law will be strictly enforced against them.

"I cannot help remarking how much it is to be regretted, both for the comfort and sanitary well-being of the residents in Naas, that the important duty of scavenging the streets and lanes of the town is so persistently ignored. The condition of these during a large portion of the year is really shameful, and is certainly an encouragement to the commission of nuisance by the ignorant and poor.

"I remain, your obedient servant,

"JOSEPH SMYTH, M.D."

Chairman—Whose duty is it to cleanse those places? Is it the duty of sanitary authority or of the towns commissioners.

The Clerk—There was a letter on a similar subject from the Local Government Board which I will read :—

"SIR,—The L. G. B. acknowledge the receipt of your letter inquiring how the sanitary condition of the town is to be ascertained, and how the streets are to be cleansed, and from what source the funds for the purpose are to be provided.

"The duty of cleansing the streets is not, in the opinion of the L. G. B., transferred to the board of guardians by the Public Health Act, and therefore, as pointed out in that circular, the powers of the town commissioners in this respect continue in force, and are to be carried into execution by the same authority and in the same manner as if the Public Health Act had not been passed.

"B. BANKS."

The board made an order that Dr. Smyth's letter and the correspondence be forwardad to the Naas town commissioners.

WATERFORD UNION.

LOCUM TENEMS.

THE following was read :—

"Sir—The Local Government Board acknowledge the receipt of minutes of proceedings of the guardians on the 27th ult., from which it appears that Dr. Cutler has been appointed at a remuneration of three guineas, to act for one week as temporary substitute for Dr. Cane, Medical Officer of the Kilmackevogue Dispensary District, and at a similar remuneration for Dr. Whitty, Medical Officer of the Ullid District, who have both been granted leave of absence in consequence of illness; and the board desire to state that under the circumstances set forth, they will not object to this arrangement, but should either medical officer require an extension of leave of absence, a substitute should be appointed, who will devote all his time to the duties of one district.

By Order.

B. BANKS."

MAINTENANCE OF DISPENSARY PATIENTS IN HOSPITAL.

THE following was read :—

"Local Government Board, Dublin,
19th February, 1878.

"SIR,—The L. G. B. acknowledge the receipt of your letter of the 11th inst., and of its enclosures, in which you inquire whether the guardians can pay a sum of 18s. to to the Governors of St. Mark's Ophthalmia Hospital, Dublin, to defray the cost of the maintenance in the hospital of a man named Edward Mullen, who, it appears, was sent direct to the institution by Dr. Healy, and had not

been previously an inmate of the workhouse; and, in reply, the L. G. B. desire to state that medical officers of dispensary districts have no power to send patients requiring treatment to hospital at the expense of the Poor-rate; and the power conferred on the guardians in this respect is limited under the provisions of section 7 of the Act 25 and 26 Vic., cap. 83, to those cases of inmates of the workhouse. The board of guardians accordingly are not in a position to apply the Poor-rates to defray the expenses incurred in the present year.

"The enclosures to your letter are returned herewith as required. By order,

"B. Banks."

Mr. Dowdall—I was speaking to Dr. Healy about it, and he said he would pay the amount himself.

R. O.—The boy's father is well able to refund the money himself.

KILLALA DISPENSARY.

At the meeting of the Killala board of Guardians on Saturday, Dr. McNulty, the medical officer of the workhouse, was unanimously and cordially elected medical officer of the Killala dispensary district, in the room of Dr. Joseph Atkinson, who has accepted a medical appointment in England, and has gone to reside there.

BALLINA UNION.

SALARY AS APOTHECARY TO THE DISPENSARY MEDICAL OFFICER.

The Chairman said the resolution of the dispensary committee, increasing Dr. Scott's salary in consideration of his undertaking the duties of apothecary, came before them. He proposed that the recommendation of the committee be carried out.

Mr. Knox seconded it.

Chairman—The dispensary meeting was a very large one, and they gave the matter very full consideration, and we should have no hesitation in carrying out their recommendation.

Mr. Coolican—As additional duties are imposed, we should not ask Dr. Scott to undertake them without paying him for them.

Mr. Walshe asked did such an arrangement as was now proposed exist in any other union?

The Clerk was not aware.

Mr. Knox said Dr. Atkinson had held the appointment of apothecary since the formation of the union, and that on his demise it was proposed to abolish that office and give the compounding to Dr. Scott at an increase of salary.

Mr. Walshe understood dispensary medical officers took office on the understanding that they were to compound their own medicines.

Mr. Knox.—Dr. Scott would have done so had not Dr. Atkinson been in office when he was appointed.

Mr. Walshe said it would be making a bad precedent if medical officers were to be paid for compounding their medicines. If they were not adequately paid for the discharge of their duties as a whole, why not their salaries be increased? but they should not be paid for compounding the medicines for themselves, as that was not done elsewhere, and would be establishing an inconvenient precedent.

The Chairman said this board was not going to make a precedent. If Dr. Scott resigned tomorrow, his successor would be appointed in the ordinary way; it was only because additional duties were being imposed on Dr. Scott that his salary was to be increased.

Mr. Walshe did not object to pay a medical officer well, if the effect of that would be that the medical officer would look closely after the medicines, see that they were kept from damp, and in a condition fit for the poor people they were intended for. The doctors thus looking after their medicines would result in a great saving to the ratepayers, more than the increased salary which might be paid to them.

The Chairman concurred in Mr. Walshe' observations, and having put the question declared that the board adopted the resolution of the dispensary committee, unanimously giving Dr. Scott £30 a year in consideration of his undertaking to compound the medicines.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF FEBRUARY, 1878.

February 2nd.—Jackson, James, Cara, Clows, co. Monaghan, M.B. Univ. Dub. 1875, Lic. 1874 and Lic. Mid. 1876 R. Coll. Surg. Irel.

16th.—Hamilton, John Robert, 4 Ulster Terrace, Stillorgan Park, co. Dublin, Lic. R. Coll. Surg. Irel. 1877, Lic. 1878 and Lic. Mid. 1878 K.Q. Coll. Phys. Irel.

20th.—Redmond, Joseph Michael, 126 Sandford Road, co. Dublin, Lic. R. Coll. Surg. Irel. 1876, Lic. 1878, and Lic. Mid. 1878, K. Q. Coll. Phys. Irel.

21st.—Leary, Edward George, Minore House, Drumclones, co. Monaghan, Lic. R. Coll. Surg. Irel. 1876, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

21st.—Armstrong, John Henry, 44 Lower Leeson Street, Dublin, M.B. Univ. Dub. 1876, Lic. R. Coll. Surg. Irel. 1877.

27th.—Arthur, Thomas Francis, Thomas Street, Waterford, Lic. R. Coll. Surg. Irel. 1876, Lic. 1878 and Lic. Mid. 1878 K. Q. Coll. Phys. Irel.

NORTH DUBLIN UNION.

ABUSE OF DISPENSARY RELIEF.

The following letter from Dr. Speedy was read:—

Dublin, 1st March, 1878.

Gentlemen,—I have again to report for your information that the tickets for dispensary relief in No. 3 Dispensary District are, in many instances, issued indiscriminately, and, in addition, the practice of filling and signing tickets by deputy has become quite common. This latter system is, I am informed, illegal; fearing that some mistake will ensue, detrimental to the deserving sick poor, I consider it my duty to place the subject under your notice. The enclosed are a few out of several tickets received in February. I have reason to believe that the practice is not confined to one or two wardens of the district.

For future guidance I would respectfully ask a ruling on this point.

My colleague and I both complain of persons well able to provide medical advice and medicine obtaining dispensary tickets.

The enclosed are two tickets recently issued, being good examples of this abuse. Catherine D——, whose husband rents the house, rated at £12 a-year, has £1 5s. 0d. weekly from the railway, besides 3s. 6d. a-day pension, and, in addition, money in the funds; in this case the *medical officer of the railway was in attendance upon this patient* when the dispensary medical officer was called in. Upon the matter being represented to the guardian who had issued the ticket that gentleman cancelled it.

The other ticket was for a man, Thomas D——, occupying the house, rated at £8. He was a cab owner, kept a cow, and had house property upon the Royal Canal. His own messenger stated that he *had seven houses*, and admitted his ability to pay. Of that I am perfectly assured. The patient expressed the opinion (not an uncommon one) that as a ratepayer he was entitled to dispensary relief.

In both these cases the individuals have had medical advice and medicine most improperly. So far as cancelling tickets it is very little use, because, in the majority of instances the patient has been attended to before the committee can meet, as in above examples.

It will be unnecessary to cancel the ticket in the latter case, as the man died this week. I am reluctant to trouble the committee on these matters, but do so on principle. I have always endeavoured to do my duty

towards the sick poor, and am not, I think, unreasonable in my views, but, assuredly, the above are typical examples of the way in which the Medical Charities Act is abused.

I am, Gentlemen,
Your obedient servant,
ALBERT SPEEDY.

The Chairman of North City
Dispensary Committee.

A discussion arose, in the course of which Mr. O'Brien (Local Government Inspector) explained that it was clearly illegal for tickets to be issued by any person but the guardians themselves or those wardens empowered to do so. He (Mr. O'Brien) had heard many complaints similar to that now made by Dr. Speedy, and the abuse was not confined to the city, but was prevalent in the rural districts. The custom of wardens leaving tickets with their assistants or clerks to fill up and issue was most decidedly an abuse which was most reprehensible, and which ought to be at once discontinued.

Dr. Speedy's letter was marked read.

Extirpation of the Left Kidney.

FROM an excerpt in *La Presse Medicale Belge* (taken from the *Bérliner Klin.*, No. 24, 1877) we learn that Professor Langenbeck has recently performed this operation in a woman thirty-four years of age. Immediately on admission into the Saint Lazarus Hospital, Berlin, the patient entreated the physicians to relieve her of a very painful tumour which began to appear in the left lumbar region eighteen months before. On inspection there was nothing particular to be seen, but on palpation a tumour could be recognised, sensible to pressure, hard, smooth, rounded, about eight centimetres in length, slightly movable, and apparently seated in the mass of lumbar muscles. The professor and his assistant having examined the urine and found it in a healthy state, rejected the diagnosis of cancer of the kidney in favour of a malignant tumour seated in the muscular structures and in the inter-muscular connective tissue of the region affected. The operation was considered to be both feasible and urgent.

Langenbeck made an incision extending from the border of the twelfth rib as far as the root of the ilium, and parallel to the vertebral column. Having divided the sub-cutaneous cellular tissue and the superficial layer of muscles, he reached one extremity of the tumour. He succeeded in separating with his finger this portion of the surrounding tissues; but at a greater depth the adhesions were so great that they could only be isolated from the tumour by using the bistoury and scissors.

When the tumour was almost completely separated, there was found fixed to its centre a sac, formed by a white cord of the size of the common carotid artery. The depth at which this cord was situated rendered its ligature a laborious operation. After the wound had been thoroughly explored in case any part of the tumour should be left behind, it was removed by the ligature, and, contrary to expectation, no hæmorrhage followed. On examining the tumour, the section of a duct was exposed with thick walls, without any contents, and in which a good sized bougie could enter for the distance of fifteen centimetres. It was the ureter and the left kidney in a degenerated state. The result of the operation was most satisfactory, and a month afterwards the patient left

THE LOCALISATION OF CEREBRAL DISEASE.

BEING THE

Gulstonian Lectures delivered before the Royal College of Physicians of London.

By DAVID FERRIER, M.D., F.R.S.

(AN ABSTRACT).

The question to be discussed, was that of whether there was a localisation of function in the different parts of the brain, and whether, therefore, the symptoms of a lesion would vary with its locality? That, as yet, there was no general agreement on the subjects, except as to a few propositions, some of which were even now contested. Our knowledge of the nervous system was behind that of other organs. There are several reasons for this, two of which are: (1), our knowledge of the morbid anatomy of the nervous system is far from being coextensive with that of its pathology; and (2) from the delicate organisation of the brain, there is a natural and continual tendency to believe that interference at any one point must tend to general functional disturbance. We can, therefore, only speculate on the intimate molecular changes which lie at the root of neuralgia, epilepsy, convulsions, &c. It was not always clear, by the inductive method of agreement, as to whether the connection was that of causation or coexistence, and it is liable to be frustrated by a plurality of causes. Organic alterations cannot always be demonstrated in an organ functionally disordered. That certain symptoms can only be causally associated with a certain lesion, unless they occur together more frequently than chance can account for. Diseases of the brain must be looked at from physiological as well as psychological aspects. Disease which produces change in the intellect, may not be accompanied by motional and sensory changes, and disease affecting motion and sensation may not affect the intellect. Beyond the great fact that the brain is the organ which is directly or indirectly diseased in insanity we are yet in the most profound state of ignorance regarding the intimate pathology of the condition. *Post-mortem* examination of the brains of the insane reveals various morbid conditions, but with the exception, perhaps of general paralysis of the insane, we have yet to find out whether there are any morbid appearances specially characteristic of special forms of mental derangement; or whether there is a definite relation between the locality of a lesion, and the symptoms observed. We cannot even be sure that the changes discoverable are the cause or the result of the disease. Until the morbid changes discoverable in the brains of the insane are translatable into their subjective significations, we cannot have a concrete or incorporate mental pathology, as distinct from mere speculation. From the fact that large portions of the brain cortex may be disorganised without causing very evident mental disturbance, and from the further fact that any one portion of the brain may be destroyed with a like negative result, the conclusion has been drawn that there is no localisation or differentiation of function, but that such part of the encephalon is a micro-encephalon capable of itself of performing all the functions appertaining to the whole. Inasmuch as a whole hemisphere may be destroyed without manifest impairment of the fundamental powers of mind, the conclusion is obvious that one hemisphere is sufficient; but there is no evidence that the same parts in both hemispheres may be destroyed without mental symptoms. It may be functional even if a unilateral lesion can occur without mental consequences if the observations made were sufficiently minute and exact, and if we had a means of accurately gauging the mental condition. The assumption that observations made on the lower vertebrates may be applied to man without qualification has done much to propagate errors and discredit that which is, after all, the sheet anchor of accurate biological and therapeutical research. The facts of clinical medicine are not sufficiently taken into account by some physiologists, and the frog-and-pigeon physiology has done much harm. It has been asserted by a distinguished authority that the theory of cross-paralysis which has been taught since the days of Aretæus is neither an

absolute rule nor an approximative generalisation. So far as we know, it is true, with the exception of some 200 cases which have been collecting since all antiquity. It is not occurring now. The great preponderance of evidence is in favour of the view of cross-paralysis. It is within the region of possibility that it may not exist in some cases, just as the viscera are sometimes transposed. It would seem that the pyramidal strands are developed subsequently to the hemispheres, and that they form the path of *voluntary* motor impulse and of secondary degenerative changes in consequence of lesions of the motor part of the brain. The localisation of functions of the brain of modern time is essentially a new growth. Hughlings-Jackson was the first to indicate the motor functions of certain convolutions, irritation of which was the cause of unilateral convulsions. The late Dr. Bright had arrived at a conclusion that unilateral convulsions, where consciousness is retained, are due to a lesion in the opposite hemisphere, and in this he was followed by Dr. S. Wilks. Hughlings-Jackson observed that convulsions were not due to transmitted influences, bnt to discharges. In the motor regions the grey matter is the essential part, as proved by the experiments of Fritsch and Hitzig. It has been asserted that it is impossible to localise the irritation, but this is not so. The recent researches of MM. Frank and Piètres have shown that the theory of physical conduction to subjacent ganglia, is altogether untenable. The grey matter reinforces excitations. With respect to the conclusions drawn from extirpation of the cortex, there is a want of unanimity among physiologists. This is owing to the fact that the results of experiments in different orders of animals are not strictly comparable with each other, or directly applicable to man. After the removal of a portion of the cortex, all movements below the purely voluntary, are more or less intact, as being more or less independently organised in the lower centres. The only essential effect of cortical lesions is paralysis of truly voluntary motion, or motion involving conscious discrimination. Thence though a dog's paw may not be paralysed as an organ of locomotion, it is permanently paralysed for all purposes for which it is used as a hand. As physiological experiments demand strict topographical accuracy, it is essential the same be observed in the case of disease in man. From deficiency in this respect most of the older records of cerebral disease are valueless. Physiological experiment at present is far ahead of pathological knowledge, and but for experimental physiology pathology would not have succeeded in establishing much beyond general indications.

Lesions of the frontal lobe are not accompanied by motional or sensorial disturbances in monkeys. Many clinical cases are on record of both sudden and slowly progressing disease of the perforated lobes without paralysis of either sensation or motion. The lecturer then gave details of the famous American crowbar case, where a crowbar an inch-and-a-quarter in diameter, and three feet and seven inches in length, and weighing thirteen and a quarter pounds, was driven under the zygomatic arch, and through the left frontal region, with a distinct orifice of entrance and exit. Photographs of the bar and of the skull were exhibited. After the man had recovered from his temporary surprise, he walked up a long flight of stairs and gave a distinct account of the accident. He lived twelve years afterwards, and died in epileptic convulsions. The only change in him was a mental one. From being a steady, industrious, hard-headed foreman, he became quite unfit for his place. He was capricious, vacillating, and demoralised. He was, as it were, a boy in full possession of his passions. In fact, he was morally deteriorated, and his friends said he was not himself at all. Lesions made in the frontal lobes of monkeys were followed by a distinct diminution of their intelligence and curiosity, and of their faculty of attention; and they were either motionless, or their movements were purposeless, and merely restlessness. Similar lesions on man were followed by like symptoms, and by the impairment of attention, so far as they have been observed.

RUPTURE OF THE TENDON OF THE GLUTEUS MAXIMUS. (*a*)

By ROBERT McDONNELL, M.D., F.R.S.,
President of the Royal College of Surgeons, Ireland.

The patient, he said, had been seen by several members of the Society, and might be regarded as one of more than usual interest, inasmuch as he had not met with any surgeon in Dublin who had seen an example of the accident, and had not been able to find anywhere a recorded account of it. The history of the case he now desired to lay before the Society was as follows:—

Martin Brady, æt. 63, a farmer, was admitted into Steevens's Hospital on the 26th of December, 1877. The family history was favourable, there being no trace of hereditary or of syphilitic taint; the patient had never suffered from eruptive or any acute disease, had been of temperate habits, and had always enjoyed excellent health. He was a tall fine-looking man, hale, and remarkably well built, and was about 6 feet 2 inches in height. The account which he gave of the accident was exceedingly graphic. It appeared that he was accompanying one of his own carts home from a field. The cart was heavily laden behind, light on the horse's back. To prevent the cart toppling backwards he ran to catch hold of the long shafts projecting from behind when passing through a gateway, but the strain being overwhelming the cart was thrown back, and he was brought violently down to an almost sitting position, and then made a strong effort to throw the cart forward, the man being exactly in the position which was calculated to put the greatest strain upon the gluteus maximus muscle. At that moment the patient stated that he felt as if he had received a severe blow from a stone and heard a sharp snap, which he described as like a clap of the hands. He immediately experienced acute pain about the fold of the left nates, which so disabled him that he fell on the ground. Having limped about for the space of an hour he was obliged to return home, took to his bed, and remained unable to work, and in considerable pain for some days. There was extensive swelling and ecchymosis; he was "black and blue from the waist down to the ham." He was confined to bed for six weeks, at the end of which time, the swelling having disappeared and the pain subsided, he was able to get up, but found he had quite lost the use of the leg, and felt, on movement, a stinging pain down the back of the thigh and in the skin. He was seen shortly after the accident by the local medical practitioner, who, however, did not pursue any treatment. Although the accident occurred on the 5th of October it was not until the 24th of December that the patient came under observation at Steevens's Hospital. There could no longer be any doubt as to the nature of the accident. In the gluteal region the gluteus maximus on the side of the injury was soft, flabby, and, in fact, completely paralysed; while on the other side it stood out prominently, was plump, strong, and well developed. The difference to the eye was very striking. Besides, however, the paralysis of the gluteus maximus muscle, near to the insertion where the muscle joins its tendinous expansion from the line of the great trochanter and the linea aspera, there was a thickened welt indicating the place where the process of union was commencing to take place. Accompanying these symptoms there was a marked paralysis of the limb. That palsy was much more complete as affecting the extensor muscles of the leg. He could not raise his toes, and in attempting to walk he tripped, but to obviate the inconvenience arising from this the patient devised a bandage which went round his neck and extended down to and raised the toes off the ground. Observing the paralysis of these muscles so markedly, it occurred to me that the sciatic nerve had been injured; but on examination, it was found that all ordinary sensibility was quite perfect. The patient could

(*a*) Read before the Surgical Society of Ireland. The discussion will be found on page 233.

distinguish readily heat and cold, and felt normally the compass points applied to any part of the lower limb. Besides, the muscles of the posterior part of the limb were not paralysed to the same degree. As to the extensor muscles of the thigh, he could raise the limb and kick with it violently and strongly. The account which the patient gave of the accident itself, as to the hearing of the snap, and the impression that he had received a sudden blow upon the limb, coincided with the account which patients gave of ruptures of tendons elsewhere. He hoped to have been able to exhibit a photograph of the gluteal region of the patient, but he was accidentally prevented from doing so. He had searched through the works in which ruptures of tendons were alluded to, but had failed to find any account of the rupture of the tendon of the gluteus maximus muscle, and although that was so very powerful a muscle, they could easily understand why the rupture of that tendon should not be very common. It was rare, he fancied, for persons to be in the exact position in which the patient in this case was, and to put such an immense strain upon the muscle in the way in which the tendon was most likely to give way. The circumstances of the accident he had described, were just such as would put the greatest force and strain upon the muscle. It appeared so far as one could make out from careful examination, to have torn at the part where the tendinous expansion and the muscular fibres meet. The commonest form of ruptured tendon met with, was that of the tendo-achilles, but it did not appear in the recorded account of that accident, that that tendon gave way with any great constancy at any point. Boyer had described a case in which rupture of this tendon occurred on each limb in the same patient, yet at a different part on each side. In the last case of rupture which came under his observation, the accident occurred rather high up, and was evidently a rupture at the part where the tendon and the muscular fibres meet. However, there did not appear to be any exact rule with regard to the place where the muscle would give way. A remarkable case was reported by Mr. Tufnell, in the Proceedings of the Pathological Society for 1862, in which a soldier of the Scot's Greys, met with the curious accident of having his thumb bitten off, and the tendons dragged out from their attachments, and in that case, they gave way at the part where the tendons were attached to the muscle. In cases where the tendons were artificially torn from the muscles, after death, the usual place of rupture is at the junction of the muscular and tendinous part. In Mr. Tufnell's case, the accident occurred in this way:—A loose horse being in the barrack-yard at Newbridge, the patient ran before him to prevent his passing out through the gate, standing with both hands and arms held out. The animal as he darted by, made one snap at his hand, and, seizing the thumb in his teeth, amputated it in an oblique direction, through the metacarpal bone. Hardly a drop of blood escaped, and the line of incision was so regular that nothing required to be done but to shorten the bone with nippers, and close in the edge of the wound by adhesive plaister. Cold lotions were laid over the arm, and the man rapidly recovered without the slightest ill consequence, beyond the loss of the member thus suddenly detached.

Mr. Tufnell exhibited the specimen at the Pathological Society. At the top of the joint, the tendons were pulled out very much, as cooks took out the tendons of the drumstick of the turkey, by tearing it away from its muscular fibres. While on the subject of the rupture of tendons, he should like to allude to a case which they had under observation some years ago in Steevens's Hospital. It was a case of injury not frequently met with, yet in this instance, occurring on both sides, rupture of the tendinous expansion of the quadriceps extensor cruris above the patella. A man named Edward Walsh, 62 years of age, a hale, well-built farmer, was admitted to hospital on the 22nd of December, 1866. The patient was sent up to Dublin to be placed under his (the President's) care, by Dr. Richard Walsh, of Ballinakill, twelve weeks after the accident had happened. In the course of a struggle with a restive horse, he was knocked over into a drain, and in making an effort to recover himself, he heard a snap, and the left leg gave way under him. Being a man of strong will, he jumped upon the good leg, and made another attempt to master the horse, but he was again knocked down, and then the other tendon gave way. Immediately after the accident, he placed himself in the hands of a celebrated bone-setter in the locality, and he recommended exercise, and the limb was subjected to passive motion. When he came under notice at Steevens's Hospital, twelve weeks afterwards, there could be no doubt about the diagnosis. When the limb was bent, the end of the femur projected so obviously, that its outline could be seen, but when the limb was straightened, the fingers could be pushed above the patella, so as to go into the inside of the joint; in fact, the inside of the joint could be examined with nothing intervening but the skin. A small portion on one side of the tendon of the vastus externus alone remained untorn. He need scarcely say, that that patient coming to the hospital twelve weeks after the accident, and having been subjected to treatment, the very reverse of that suitable to the case made a very imperfect recovery. He was able to walk by the aid of sticks, and wore splints made to keep his limbs straight. That patient left hospital on the 3rd of February following, not much improved. Another case of rupture of a tendon occurring among his patients at Steevens's Hospital, was an instance of rupture of the long head of the biceps. That occurred in a man named Peter Langan, 40 years of age, who was admitted to hospital on the 18th of April, 1868. The notes of the case were taken by Dr. Ward, who was then his (the President's) resident, and who was now M.P. for Galway. In making violent exertion to reach something under his bed, the patient gave the arm a twist, and immediately felt something give way. When the patient came under observation at Steevens's Hospital, any attempt at flexing the arm was accompanied by remarkable fulness, and one could feel the tendon of the long head in the bicipital groove running down under the finger. A careful examination failed to find any rupture of the short head.

The way in which the belly of the muscle was thrown into prominence at that part, left little doubt that the tendon was ruptured there. They must, however, always remain in doubt about these cases, and they also knew that a consequence of chronic rheumatic arthritis, as Mr. Adams had carefully pointed out, the biceps tendon would become frayed and eroded away, and finally give way, and became adherent in the bicepital groove. In that patient, however, there was no chronic rheumatic arthritis, and therefore, they could not attribute the giving way of the tendon to that affection. Boyer relates a case of rupture of the ligamentum patellæ, which seemed to be a rarer form of accident than the rupture above the patella. The case Boyer gave, was that of a young man, twenty-five years of age.

The snap or rupture of a tendon seems to be very constantly accompanied by a sensation, as if the patient had received a smart blow or kick. The common French name for the supposed rupture of the tendon of the plantaris longus, is *Coup de fouet*, so much does it give the patient the idea of a smart blow from rod or riding-whip.

As to such cases as that he now spoke of, and as they did not meet with such cases often, they must be treated on general principles. The patient had been kept quiet, but allowed to move about with the limb straight, so as to keep the ends in apposition. He was now able to walk a good deal better than when he entered hospital. The paralysis of the limb had very much improved, and the patient was now able to walk very well with one stick. The complete paralysis of the muscle was remarkable, and looked almost like an effort on the part of Nature to take tension off the muscle, to allow it to remain passive and quiescent while union is going on. He (the President) said in conclusion, that he would be very glad to hear from any member who might have had an opportunity of seeing that case, whether he knew of any recorded case of the

kind. He (the President) had not himself been able to light upon any recorded case of rupture of the gluteus maximus. He was also happy to say that Mr. Colles, Mr. Richardson, and Mr. Tufnell, and others, had seen this case as one, if not unique, at least of unusual occurrence.

Clinical Records.

JERVIS STREET HOSPITAL, DUBLIN.

Case of Poisoning by Aconite—Recovery.

Under the care of Dr. MELDON.

(Reported by Mr. J. S. DUIGENAM, Resident).

On Thursday, the 7th of February, a gentleman, J—— McG——, twenty-two years of age, came to Jervis Street Hospital, and produced a bottle labelled "Liniment—poison." He stated that about five minutes previously, he had taken about two ounces of it. On examining the bottle I came to the conclusion it was aconite. He drank the liniment at 9·30 a.m. A few moments afterwards, the occurrence of severe gastric pain led him to discover his mistake. I immediately gave him an emetic with castor oil, ordered coffee, and sent for Dr. Meldon, the surgeon on duty. By this time, he complained of a burning pain in the stomach, œsophagus, mouth, and tongue, tingling sensation in the fingers, feet, and lips; his pupils were very much dilated, the lips swollen, and the extremities cold. Dr. Meldon arrived at 10·15 a.m., and ordered brandy, coffee, charcoal, and ammonia. The coffee, which I previously had prepared, he got at once, subsequently the brandy, animal charcoal, and ammonia. Owing to the vomiting, however, very little of these remedies was retained.

At 10·30 he complained of blindness, which was immediately followed by tetanic spasm, and then complete insensibility. The lips were now kept wet with brandy, and ammonia held to the nose, and in a few moments sensibility returned, and the patient was able to speak. Five minutes later, the pulse became quick and weak, and another tetanic spasm, more violent than the last, was followed by apparently total failure of the heart's action, and complete insensibility, during which the respiration was invisible, and death seemed inevitable. Dr. Meldon now administered an enema of brandy, while Dr. Kilgarriff commenced artificial respiration, and Dr. Hughes applied the galvanic battery. Fully five minutes were thus spent before the return of colour to the lips gave hopes that all was not yet over. A few minutes more, and he was able to swallow a few drops of brandy and ammonia. He was able to speak at 11·5 a.m., but was very weak. Several times during the next few hours artificial respiration was had recourse to. Dr. Meldon prescribed frequent enemata of equal parts of brandy and beef-tea, which were given during the day.

At 1 p.m. the pulse was only forty a minute; the pupils were widely dilated, and vomiting and diarrhœa continued, and the tingling sensation was still present in the hands and feet. A mixture was now ordered by Dr. Meldon, consisting of ether, camphor, ammonia, brandy, mucilage and water. At 1·30 p.m., he asked for a little porter, which I gave him, and which remained on his stomach, and everything which he subsequently took he retained. The tingling sensation first left the right hand and foot about six o'clock on Thursday night, and on Friday morning, only a trace was felt in the fingers of the left hand. He left the hospital on Friday night, the 8th inst., quite recovered.

Dr. Meldon, in his remarks to the students, pointed out the great difference of symptoms observed after poisoning by aconite. In some cases, the pupils have been contracted; in others, as in this, widely dilated; in some, as long as the patient retains consciousness, he can walk, as in the present case; in others, loss of power of the legs is one of the first symptoms. In some cases, no convulsions have been noticed. These differences of symptoms have even been observed when the patients have eaten of the same variety of the drug, generally when the root has been mistaken for horse-radish. Many of these differences, in Dr. Meldon's opinion, arose from the quantity of the poison taken. He also drew attention to the great difference between the root of aconite and horse-radish, as shown in the following table, taken from Mr. Bentley's paper in the *Pharmaceutical Journal*, vol. xv., p. 450, April 1856.

ACONITE.	HORSE-RADISH.
Form.—Conical in form, and tapering perceptibly (and rapidly) to a point.	*Form.*—Slightly conical at the crown; then cylindrical or nearly so, and almost of the same thickness for many inches.
Colour.—Externally coffee coloured, or more or less of an earthy-brown colour.	*Colour.*—Externally white, or with a yellow tinge.
Odour.—Merely earthy.	*Odour.*—Especially developed upon scraping, when it is very pungent and irritating.
Taste.—At first bitter, but afterwards producing a disagreeable tingling numbness.	*Taste.*—Bitter or sweet according to circumstances, but very pungent.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

STONE IN THE BLADDER.

The last meeting of this Society was distinguished by the large attendance of fellows and visitors, and the great interest taken in the paper of Sir Henry Thompson, which embraced a summary of his experience of 500 cases of operation for stone in the bladder, up to January, 1877. The calculi from each of these 500 cases were exhibited. The 500 cases were adult males, the great majority being from 50 to 70 years—the mean age 61½ years. The published experience of Cheselden, Marineau, Brodie, and Fergusson was given. The sum of similar cases treated numbered 422. Of these 422, 69 were fatal, or 16½ per cent.—*i.e.*, 1 in rather more than 6 cases. Of the 500 cases in question, 422 were by lithotrity, and 78 by lithotomy. The number of individuals operated upon was 420, several of the lithotrity patients being operated upon twice, a few three times. In all cases a considerable interval and evidence of fresh formation, mostly a newly-descended uric-acid calculus, had existed. Small phosphatic concretions, although removed by lithotrity, had not been reckoned as stone in the bladder. The chemical constitution of the calculi was as follows:—Uric acid, 313; phosphatic, 99; mixed, 81; cystic oxide, 1; pure phosphate and carbonate of lime, 2; phosphatic calculi formed on foreign bodies, 4. The mortality, accepting almost any death occurring within six weeks of the operation, was as follows:—In 422 cases of lithotrity, 32 deaths, or 1 in 13 cases; in 78 cases of lithotomy, 29 deaths, or 1 in 2¾ cases. Total, 500, with 61 deaths, or 1 death in 8½ cases. The causes of death, which were given in each case, were tabulated, compared, and contrasted in the two operations, with inferences thereupon. Accidents met with in operating by each mode were detailed, and the manner in which they were dealt with. The general inference was arrived at that it was unwise to apply, as a rule, lithotrity to any stones above moderate size; and if any calculus is sufficiently large to require what is known as the fenestrated instrument, it is better to employ lithotomy. The author had not employed such an instrument during the last ten years.

After the President had returned thanks to Sir H. Thompson, and complimented him upon his valuable and instructive paper,

Mr. CADGE (of Norwood) called the attention of members to the result of his experience, and to his opinion of these operations. He said that the 500 cases cited were remarkable for their successful results, as well as for showing the increase of

specialism, the division of labour in the profession. Mr. Cadge then entered into the respective statistics of the two operations, and said that of all persons above 50 submitted to lithotomy, 31 per cent. die; while only 8 per cent. of those submitted to lithotrity are fatal; and that according to Sir H. Thompson's experience of the two operations the effect of lithotrity has been to reduce the mortality of all cases over 50 from 31 to 12 per cent. His experience, which amounted to 230 operations, tallied closely with that of the author. Of 104 adult cases, 20 per cent. died; of 86 lithotrity cases, 8 died, or 1 in 10¾. But then, while recurrence after lithotomy was rare, it was very common after lithotrity; and Mr. Cadge put great stress upon the fact that this recurrence is one of the serious defects of lithotrity, and is due in the large majority of cases to minute portions having been overlooked. Another serious defect is the cystitis, and the continued vesical irritability and phosphatic deposit not unfrequently left after lithotrity. Sir H. Thompson has described this as unavoidable, and as the price paid for greater security to life which lithotrity affords; and he thinks it is due to the injury done to the mucous membrane by sharp fragments of stone and by continued instrumentation, and also to chronic retention of urine, which is apt to come on during lithotrity in old people. A more frequent cause, however, is the sacculated condition of bladder so frequently produced by prostatic enlargement. A calculus descending from the kidney into such a bladder is not passed, owing to the obstruction to the outflow by the enlarged prostate, but augments there. Lithotrity is resorted to, some of the fragments hide themselves in the recesses of the mucous membrane, and either set up acute inflammation which extends to the peritoneum and quickly ends fatally, or, more frequently, the bulk of the stone is removed, the patient is much improved, but a fragment or two secrete themselves in the sacs and produce chronic cystitis, encysted stone, and phosphatic deposit. It is the most frequent cause of those "scores of cases" which Sir H. Thompson has mentioned of cystitis and phosphatic deposit in old people. Thus, then there was after lithotrity a much larger class of cases which neither die nor recover than what obtains after the other operation, so that some may think that this fact almost counterbalances the greater security to life which lithotrity undoubtedly affords. His own experience convinced him that with all its drawbacks lithotrity was in careful hands capable of saving many lives, and a great boon to suffering humanity.

Mr. WEST (of Birmingham) who came from the neighbourhood of South Staffordshire, a district where much stone prevails, remarked that out of 139 cases at the Wolverhampton and Staffordshire Infirmary the mean mortality was 1 in 12·14, for cases under 40 years 1 in 16·2, and between 40 and 80, 1 in 11·5. In certain districts children were the chief sufferers, in others, adults; and he believed that many of the latter came up to London to be operated on. The cases of lithotrity, as a rule, did well, if the stone was early dealt with.

Mr. MACNAMARA referred to his practice in the N.W. provinces of India, where the number of cases of stone is very large indeed. Lithotomy had been the operation he had almost invariably performed, and he was glad to hear Sir H. Thompson say that in his last 100 cases he had reverted more to that operation than hitherto since the introduction of lithotrity. In this operation a free incision was, according to his experience, far safer, and attended with less injury to surrounding parts than a small one. When the stone was large he was in the habit of crushing it before performing lithotomy.

Sir J. FAYRER drew the attention of Sir H. Thompson to a work by a successful native lithotomist, which contains the details of 248 cases with 17 deaths.

Sir JAMES PAGET, after congratulating Sir H. Thompson for the brilliant results of his practice, said that he must confess to a general feeling in favour of lithotomy over lithotrity. A comparison of the two operations should be made with a full consideration of the incomplete and unsatisfactory results of lithotrity, often with months and years of suffering, and sometimes with recurrence of the stone. Then when to this be added the fact that at Sir Henry Thompson's hands the operation had received almost every improvement it could well have—compared with those of the present day Civiale's instruments are rough and unwieldly,—he thought that the operation was now performed under the best conditions possible, and that it was doubtful if we could look for its further improvement for some time to come. But there was scope for further improvement in lithotomy to ensure better results, especially in the after-treatment of cases. It does not admit of antiseptic treatment, but we recognised in the present day conditions of erysipelas and cellulitis as sources of danger after the operation, conditions misinterpreted in the past as "peritonitis after lithotomy," or "urinary infiltration," with no reference to their septic origin. The aim of after-treatment was definitely directed to prevent such conditions arising. Again, in past times, the operation would be undertaken on patients the state of whose liver and kidneys would now be regarded as contra-indicating it. Taking all these circumstances into consideration, he doubted if the mortality from lithotomy at the present day would be found so much larger than that after lithotrity; and, for his own part, were he to begin an active surgical life again, he would begin with lithotomy, and reserve for lithotrity only those few cases in which the calculus could be got rid of in two or three sittings. He felt sure that the mortality from lithotomy could be reduced by one-half.

After several other members had made a few remarks, which want of space will forbid us to notice Sir HENRY THOMPSON thanked the Fellows for the attention they had given to his paper. He said the relations between the two operations was by no means antagonistic. The real fact was that they were complementary to each other—allies, not enemies. Lithotrity was the handmaid of lithotomy, and each did work to which the other was incompetent, and in this view only could their respective merits be estimated. He would allude to what had fallen from Sir J. Paget, who, among those present, had perhaps most strongly declared for lithotomy; yet even Sir James thought lithotrity applicable to all those calculi which might be disposed of in two sittings. Well, that was a distinct position. The only question relative to it was one of degree; was the line to be drawn there, or was it to be drawn a little further in favour of the crushing operation? He thought lithotrity was still preferable where the stone might be crushed at three, or at most four, sittings. Beyond that he was not, as a rule, prepared to go, and at that point he should mostly prefer to cut. But then this introduced a very important subject. He agreed with Mr. Napier that the real want was the early discovery of stone, and this it had been a leading object of his life to teach. Every calculus ought to be found when it was of that size for which the two sittings would suffice to crush. Very rarely indeed was it not associated with symptoms which clearly showed its presence. Then, as to the question of the recurrence of stone, it was not fair, nay, more, it was not true, that the recurrence was due in all cases to the operation of lithotrity. For example, when a uric acid stone re-appeared some years after an operation for crushing, no one could for a moment suppose that this proceeding could be held accountable for the new product. What happened when lithotomy was the only operation? And what happened in the cases of diseased bladders which now lived to discredit lithotrity? Why, the patient in either case often succumbed to the cutting operations, and did not live to produce a third or even a fourth stone.

SURGICAL SOCIETY OF IRELAND.

THE Seventh Meeting of the Session took place on Friday evening, March 1st. The President of the College, Dr. ROBERT MCDONNELL, F.R.S., in the chair.

The minutes of the previous meeting having been read by Mr. B. Wills Richardson, Hon. Sec., and confirmed, the President vacated the chair, which was taken by Mr. Colles, senior member of Council of the Society present.

The PRESIDENT then made a communication to the Society, on the subject of a case of

RUPTURE OF THE TENDON OF THE GLUTEUS MAXIMUS,

which will be found on page 230.

The CHAIRMAN said the case was certainly a very extraordinary one, especially when it was connected with the paralysis, and whether rupture of the tendon would go to produce that it was very hard to understand. Certainly the patient's foot dropped as if the muscles had lost all their power. The flattened nates were very remarkable, for the muscle was almost gone, it was so very much wasted. The rest of the limb seemed to keep its shape very well.

Mr. H. G. CROLY said he had not had an opportunity of seeing the case, the facts of which the President had communicated to the Society, nor did he (Mr. Croly) know of any recorded case of rupture of the tendon of the gluteus maximus. But it struck him that the paralysis might be explained in this way: that the great violence which was necessary to rupture so powerful a tendon, might also have stretched or partially torn the sciatic nerve, as the distance from the nerve to the tendon was not great. Of the rupture of other tendons, to which the President had alluded, he (Mr. Croly) had seen a few examples. About two years since, he had a case of rupture of the ligamentum patellæ. A gentleman in jumping off a car, fell and ruptured the ligamentum patellæ. He got a kind of splint made for him of vulcanised india-rubber—a kind of imitation of the ligamentum patellæ—and that enabled the patient to get about very well, but he was still very much disabled. Some time ago, he had a case of rupture of the tendo-achilles in a man who was thrown out of a baker's cart. On examining the man, he could find nothing wrong with his ankle, but on putting his finger behind the tendo-achilles at its narrowest part, there was a decided gap. The tendon subsequently united very well by proper appliances, keeping the parts in position. This winter he had a case of rupture of the plantaris. The patient was a clergyman, and on going up the steps of his church, he turned round suddenly to see if anyone had given him a blow of a stone in the calf of the leg. As he saw no one near him, he rubbed his leg. Subsequently, he consulted a medical practitioner, who gave him a liniment to rub on the leg, which, however, continued very painful. He afterwards consulted him (Mr. Croly). From the cases he had seen of rupture of the plantaris tendon, he thought the tendon generally ruptured about four inches up from the os calcis, and not at all near to the belly of the muscle. Of course that was a well-known accident in ballet-dancers.

Dr. BARTON said he had lately met with a case which illustrated some of the points to which the President had referred in his account of his very remarkable and interesting case; a case undoubtedly, as in cases about the hip-joint, where the symptoms were very puzzling. The case to which he (Dr. Barton) now wished to allude was a very interesting one. The facts were as follow:—A man was engaged cleaning a window at a house in Merrion Square, not far from his (the speaker's) own house, and had only just stepped out on the window stool when he fell off. He was very soon on the spot, and saw the man, who was then suffering from concussion of the brain. He was evidently in great pain, and only partially alive to impressions. When moved, he referred the pain to the right gluteal region. He examined the spot immediately afterwards, and there found swelling, which appeared to him to be ecchymosis, about the size of a closed fist at the gluteus maximus muscle on the right side. The man was admitted the same evening to the Adelaide Hospital, where there was ample opportunity afforded him (Dr. Barton) of examining him from day to day, and taking notes of his case. In the course of two or three days, the patient recovered from the other injuries, which were not very serious, and then the injury to the hip was plainly to be demonstrated. He could not stand without good firm support. Upon the right leg he could not stand at all, and immediately he put it under him it gave way at once, and the man cried out with pain. On examining him behind, they saw, as the President had remarked in his case, only in a different degree, the same flattening of the nates. Although the gluteus maximus was not atrophied, it had lost its tone, and the lower edge no longer stood out, but was almost flattened. As he attempted to stand, the patient was pressed to try and throw the muscle into action, but it would not be thrown into action: it remained flat, while the other side stood out in marked contrast. And then as one stood beside him, and asked the patient to perform the various motions of the limb, while he could flex and extend tolerably well, and without pain, the rotation outwards was the one motion which he could not do. He could rotate inwards without any pain, but the moment he rotated outwards it gave him pain. He had many of the symptoms of a case of inflammation of the hip-joint. Dr. Barton said he argued from that there had been some rupture of the rotators outwards; the fibres had been ruptured, and it occurred to him, therefore, to test the fact whether the gluteus maximus tendon had been ruptured. He thought, however, as the case went on, that it was pretty plain that the tendon itself had not been ruptured; at least, we could feel the tendon gliding over its insertion pretty well. But, perhaps some of the fibres of the gluteus maximus, or perhaps a portion of the muscular structure where it was attached to the fascia had given way. It also occurred to him, whether some of the rotators outwards had not been ruptured; but that of course could only be conjecture. The case went on very satisfactorily. Rest was the only treatment adopted, and that had succeeded. The patient had gone to the Convalescent Home, and he was now able to walk about with a strong stick. He had not seen him for a week or two, but when he left hospital, he was gradually regaining power in the ruptured muscles of the hip. The President's case, and also the one he (Dr. Barton) had alluded to, together illustrated the rupture or injury of muscular structures about the hip, and he thought showed that it could occur in different degrees, and that, perhaps the muscular structure was also more or less engaged as well as the tendon. In Dr. M'Donnell's case, it appeared that the tendon was more directly engaged; but of course they had not the advantage of a demonstration on that point. It might be that the muscle was considerably torn in the first instance also. In his (Dr. Barton's) case, the ecchymosis was evidenced afterwards by the discolouration, which had been gradually and slowly absorbed. He felt that the Society was very much indebted to the President for bringing forward his case, which was one of great interest.

Dr. MAPOTHER said he had listened to the account of the President's case with very great interest indeed. It seemed to him that the President had admirably described the mechanism of which the accident had occurred. He had also shown that the position of the man at the time was a very unusual one; otherwise, they might suppose that the gluteus maximus, which was enormously developed in the human subject, for the purpose of preserving the erect position, would be more frequently ruptured. He thought, as the President mentioned in the detail of his case, the absence of ecchymosis in the ridge or near the great trochanter which the President had described, would seem to show that it was formed by the ruptured tendon. There was no doubt, that during life, tendons ruptured much more frequently than

---

The PRESIDENT—Pardon me. There was extensive ecchymosis.

Dr. MAPOTHER—But still, there was a ridge.

The PRESIDENT—Yes; a distinct ridge.

Dr. MAPOTHER continued to say that ruptured tendons were much more frequent during life, while after death, on the contrary, muscles gave way very easily. It was an interesting fact worth mentioning, that at the time of death muscles gave way just at the point of junction between the tendon and the muscle. He remembered reading of a case in the reports of the Surgical Society for about the year 1840, of rupture of the long tendon of the biceps, described by Dr. Bellingham. It was considered a most unusual occurrence at that time, and in that case there was an absence of rheumatic change in that tendon. The accident occurred in a young man, and was caused by sudden concussion. As to the accident mentioned by the President, in which he said he hoped for the union of the divided tendon, the prospect of that appeared to be not very favourable. It was not likely that any extensive fibrous matter would be thrown out to unite the fibrous tendon. He happened to know twelve or thirteen years ago, of a case of rupture of the tendon of the quadriceps muscle above the patella. That occurred as a gentleman was walking down high steps. They knew, as in Dr. Douglass's case, that generally in those cases the fall was backwards and not forwards.

Dr. HENRY KENNEDY said that in the course of his life he was cognisant of three cases in which it was said that the plantaris had given way. It was remarkable about those cases that the persons were young, and the accident occurred while they were dancing. They had the idea that they were struck from behind—rather an unpleasant idea, especially when there was a person standing close beside. In those cases the recovery was exceedingly slow. With one of those cases he had a great deal to do, and he certainly recollected that the strapping treatment gave most labour, and that it occupied many weeks before they recovered. The accidents were referred to the gastrocnemius muscle, where the muscle became tendinous. It was more probable that some of the fibres of the gastrocnemius had given way. Might he allude to an accident which occurred to a famous dignitary of our own city? In that case he believed that the muscle separated from the tendon above the patella on both sides. On one leg the accident was very severe indeed, and this leg is very much worse than the other. It was exactly such an accident as the Presi-

dent had so well brought under the notice of the Society that evening.

Dr. BIGGER remarked that there was one point in the case brought forward, which would receive a curious illustration from a circumstance which occurred in the practice of Mr. Carmichael. A man who had an aneurism of the gluteal artery sat down upon a knife, and the knife perforated the artery. He was not sure whether the case was published or not, but he was sure that certain circumstances of it bore out some of the points mentioned by the President. After that man was operated upon and the artery tied, and after he had recovered from the injury, he, for a very long time, dropped all his toes, and had very great difficulty in trying to walk. He (Dr. Bigger) did not believe in that case that any nerves of any size were injured, but pressure on the sciatic nerve might have caused the inability to raise the toes of which he had spoken. The patient recovered perfectly, however, after several months.

Dr. CHARLES BENSON mentioned a case of what at the time he believed to be a rupture of the plantaris which occurred to himself one day. He was walking quickly along one of the by-streets of the city, when he thought he felt a blow at the back of the leg, which he was quite sure had been given by a stone or a stick, and he looked about to see who had struck him, but he could not see anyone. He at once concluded that his plantaris was ruptured—an injury he had so often read of and had sometimes seen. He called a cab and returned home as quickly as possible, and, as well as he could, and laid himself up for, as he supposed, a very long nursing. He had crutches for moving about, and had his leg bandaged up carefully. The blow felt pretty high up—certainly about midway between the heel and the ham. He was greatly delighted, however, after four or five days—certainly before the end of a week—on trying how he could walk, to find that he could do so as well as ever. There was scarcely the slightest inconvenience, so he concluded that the plantaris could not have been ruptured. He was sure it was such a case as the President alluded to, where some of the fibres of the gastrocnemius muscle—some fibres of that kind had been ruptured, probably high enough up to be at the part where the muscles and the tendon unite. Some of the fibres in that place gave way probably, and most likely it was only the tendinous fibres next the muscle. There was no appearance of extravasation and ecchymosis observable in the part at the time, and he was greatly delighted that the alarm which he felt was perfectly groundless.

Mr. B. WILLS RICHARDSON had really nothing to say, except to confirm the observation of the President as to the remarkable condition of the patient—at least, he (Mr. Richardson) only saw him at a late period after the accident. The gluteus maximus was much wasted, and the leg was in that peculiar condition to which the President had alluded. He (Mr. Richardson) had no doubt whatever that rupture had taken place in the gluteal region, and, as the President saw the case not very long after the accident, and, from his description of the ridge that corresponded to the tendon, he (Mr. Richardson) could only conclude that the rupture must have been in that locality.

The PRESIDENT said, in reply, with regard to the observations of Mr. Croly about the paralysis depending upon some rupture or injury to the nerve, he could not adopt that view for the reasons he had already given. He thought that if the nerve were in any degree torn, or blood effused into its texture, at the time of the injury, as it was a compound nerve with both motor and sensitive fibres, they would expect to find some paralysis of sensation in the lower limb, as well as some paralysis of motion, while there was nothing of the kind. Naturally, the first thing that occurred to one was that the nerve might be lacerated or stretched. At the same time he observed that not only were the tactile and thermal impressions of the lower limb quite unaltered, but that tickling of the sole produced reflex movements of the muscles. Therefore, taking into account that they had the tactile and thermic impressions quite untouched, as well as the reflex phenomena quite vigorously produced on tickling the sole, he thought they must regard it as one of those forms of reflex paralysis which they knew sometimes occur. Sir James Paget had given some cases in which a severe contusion had been followed by paralysis of muscles in the neighbourhood. He (the President) thought that the case he had related must be a case of that kind. They knew that the nerves and blood-vessels were capable of undergoing a great deal of extension without giving way. Dr. Barton had detailed a very interesting case, although he (the President) could hardly regard it as exactly in the same category of cases as his; Dr. Barton's case was one of contusion more than pure rupture. It was not improbable that some of the fibres might have been torn in the process of the contusion of the limb, and the ecchymosis might be due to that. He (the President) quite agreed that these things must be very much matters of degree, and hence it was that it was impossible to speak positively as regards the prognosis in these cases. Tendons might be torn more or less completely, and a few fibres remaining holding the ends of the tendons in tolerable apposition with each other, would make the case much more hopeful for recovery. He had seen one case of rupture of the tendo achilles in which the rupture was where the tendon was narrow, was quite complete, and where the forefinger could be sunk in between the ends as distinctly as when it is divided subcutaneously by the tenotomy knife. In another case, higher up this was not so distinct; and, in a third which came under his observation, it was obviously at the connection of the tendinous part with the muscular. In that last case there was excruciating pain; the muscles seemed to have been thrown into a state of spasm. The patient in that case was a gentleman, who received the injury at Lansdowne Road railway station, and had to walk a considerable distance before he could get a cab. For some days the spasm of the muscle was extreme; there was cramp accompanied by violent pain, which engaged that part near the junction of the muscle and tendon. It seemed to him that those cases varied very much; they must regard them as differing in degree and differing in the localities where they were likely to occur. With reference to what Dr. Benson and Dr. Kennedy had said, the observations were very much to the point. They knew that the accident was particularly likely to happen in dancing, and John Hunter met with it in this way. Monro, in his interesting account of it, described the curious sensation of having received a blow or a kick, and also of the heel having gone down through a hole in the floor. The sensation of having received a blow was so common, that a person had turned round and struck the person behind him because he thought that person had given him a kick. Upon that point Dr. Benson's own case was one of peculiar interest. He (the President) had seen cases where he had very little doubt about pronouncing them as ruptures of the plantaris, but he admitted that the diagnosis had not been verified by dissection. He thought they must conclude from the excellent practical observations of Dr. Benson, that his case was merely a rupture of the fibres in that locality, giving rise to the supposition that the plantaris had given way.

Dr. L. BIGGER then exhibited

A NUMBER OF SAWS FOR USE IN AMPUTATIONS, ETC.,

and said: In presenting for the consideration of the Society a new form of saw to be used for the removal of portions of the skull, he did not wish to throw any slight, or derogate from the merits of instruments for similar purposes which have preceded him, for all have their merits, and in particular cases there is hardly one which has not its own *peculiar* merits. The old trepan was a wonderful instrument for its time; but the saw being circular, and considerable force being required to impel it through the bone, it was dangerous, and might inflict the very injury it was intended to remove. Then it was improved by a centre pin, which formed a centre fulcrum, round which the saw worked with greater steadiness and certainty, and which pin could, by a contrivance in the handle, be gradually withdrawn as the saw cut deeper, so as not to drive the circular cut portion down on the brain. Surgeons even at a very remote period felt that practically they were not satisfied with the working of these instruments, and various attempts are to be found in the records of ancient armamentaria, of very near approaches to the short saws brought into use by that excellent surgeon, Mr. Hey, of Leeds. He, practising in a district where powerful machinery was continually causing fearful fractures and injuries, felt that the trephine was not always competent to fulfil the intentions of the surgeon, and he designed the saws known by his name. Now this little saw was a manifest step in advance, and was warmly hailed by practical men, because it could effect purposes which the trephine could not, as in severing the base of depressed angular fractures, making simple incisions through bone to evacuate blood, or fluid, &c. Very little advance was made from this time, though he saw in Paris some instruments of a very complicated nature made to cut through the skull by

means of a wheel-saw cutting on edge, the entire ponderous instrument being prevented from giving undue pressure by being supported by a jointed leg, applied to some sound part of the head. The name of the inventor had escaped his memory. The saw now presented, he hoped, would make one little step further in this branch of surgery, for it can do more than the trephine, and it can do everything that Hey's saws could do with greater facility, and enable the surgeon to remove a portion of bone, because it can more readily detach the entire piece. The instrument is nine inches long, having a handle borrowed from the horseman's dagger, revolving on an octagon, which can be securely fixed in any desired position by a thumbscrew—this portion is four inches. A polished steel cylindrical shaft, four inches long, proceeds from this, terminating in a rifled elevator. Between this and the shaft the cylinder is made a little bulbous and hollow to contain a spiral spring, which can be retracted by a very minute button. Easily acted on by the thumb-nail, this withdraws or protrudes a steel pin, which passes at will through an aperture in a stemmed cramp, which is crossed by another aperture at right angles, so as to permit it to rotate, or become fixed in four positions. The saws, of nearly the form of half a crescent, are little more than half-an-inch in breadth, and 1¾ inch long, with teeth on both sides, cutting both on the convex and concave sides, and are secured in the clamp by a thumbscrew passing through an aperture in their centre. When the saw is fixed straight in the line of the handle, it can be used as Hey's saws, and possesses much more power from the good grip on the handle. As soon as it has perforated the bone at any point, the saw is made to turn laterally, and locked by the spiral spring, and thus a new power comes into play. The saw-point is passed into the aperture, and an immense lever power is gained by a hinged cushion of vulcanised india-rubber, each half of which is about an inch in thickness, with a semicircular groove in each part, lined with a half section of brass tubing, in which the steel shaft of the saw is placed, and by lateral action on the strong handle with one hand, whilst the other presses firmly on the closed cushion supported on the head, the inner or concave saw-edge is made to work, cutting the bone with the greatest facility, in the direction of the first cut. Another cut, at an angle with the first, with the same secondary manœuvre, will divide the bone clean to the angle, and perpendicular to the surface. A third cut will free a triangle of any form the operator may wish, and which, being perfectly free, is easily removed without any danger to the structures beneath. The value of the perforated cushion is that it gives a firm *point d'appui* to work the saw on, and in case of an angular or branched fracture of the cranium, the saw can be used through it to cut across the base of the fracture without exercising any undue pressure on the part where the saw is working. The advantages derivable from this saw may be shortly stated, viz., that by a simple incision it can liberate blood or any other fluid effused. By an angular one of any length cut without pressure, it can do the same more effectually, and give room for searching over a considerable space. The cutting with the concavity of the saw, raises, in place of depressing, the bone. The sections can be made quite perpendicular to the surface. The handle revolves to suit convenience, and fixes firmly in any position. A long acute triangle will fill up with bone—as happened in the practice of the author—a circumstance which never happens in trephining, although there is an attempt, nor in removal of large portions of bone approaching the form of the equilateral triangle. This saw, although specially designed for cranial sections, will act well in the removal of sequestra from the long bones. [At the request of several members of the Society, the action of the saw was shown by the author.]

Dr. BIGGER also placed before the Society some saws, which he had previously shown, for amputation and resection, and showed their working. He also showed an Archimedean drill, which he had found useful in perforating into the mastoid cells, which acted well, very similar to a smaller and less powerful instrument used by dentists.

The PRESIDENT thought the saw shown by Mr. Bigger a very ingenious instrument. It had the immense merit of being simple, and capable of having great power brought to bear upon it. With reference to circular saws, he might remark that that made by Charrière, and which consisted of a series of wheels, was a perfectly useless toy. Most circular saws failed from our not being able to apply sufficient force to them. The saw shown by Dr. Bigger seemed capable of being applied with sufficient force.

Mr. O'GRADY said that the most satisfactory test would be for Dr. Bigger to remove a portion of a skull that he would mark with ink, in the presence of the Society. They were all more or less acquainted with the working of the trephine; but the mode he suggested would be a practical way of showing the working of Dr. Bigger's saw.

Mr. CROLY said that the saw called by Dr. Bigger, Hey's saw, was not Hey's saw at all, but was one that Hey gave the credit of to Mr. Cockle, of Pontefract. One of the other short-bladed saws shown by Dr. Bigger, was in reality Scultetus's saw, whose name Hey mentions in connection with it.

Dr. BIGGER.—Is not the saw shown by me as Hey's saw, the one adopted by Hey?

Mr. CROLY admitted that it was. With reference to the first saw, it was an extremely nice instrument. He remembered hearing of it often, but had never had the pleasure of seeing it before that evening; but of course he would like to work it on a bone before he would express an opinion as to its being better than the others in use. He thought the one intended to act as a trephine was also a very ingenious instrument, but there was one point that he was sure must strike any one in connection with the use of the last-named saw, and that was that the size of the piece of bone to come out must greatly depend upon the extent of the injury. They could take out a nice little bit of bone and say that the periosteum would not be disturbed, when they knew that must be dependent on the cause or nature of the injury, and where the pericranium was detached to a great extent, and where they had to get in an elevator, they could not cut out a piece of bone so as to suit the saw. It was a very ingenious instrument, and he had no doubt it would be useful in another case.

Mr. RICHARDSON inquired what Dr. Bigger claimed as his own invention in the case of the amputation frame saw.

Dr. BIGGER said, the form of the instrument altogether.

Mr. RICHARDSON said that the frame of the saw was illustrated by Ambrose Parè, and by Scultetus, but the arrangement of the handle was different. With reference to the bit and brace alluded to by Dr. Bigger, it should be recollected that the old trepan was frequently worked as a bit-and-brace, and it was given up on account of its danger. He had himself illustrated (in the *Dub. Hosp. Gazette* for February 1, 1857) an Archimedean drill for perforating bone. It was almost identical with the one exhibited by Dr. Bigger, but had a small fly-wheel for rendering its action more even and steady, in, for instance, drilling the tibia to discharge an abscess.

Mr. F. T. PORTER asked Dr. Bigger if he had tried that instrument in disease of the antrum?

Dr. BIGGER.—I have, once, and it acted well.

The PRESIDENT agreed with Mr. Richardson there had been a good deal of claim for novelty for surgical saws which had long been in use, for instance, by ivory turners, for cutting round corners, and so on. He thought Dr. Bigger should rest his fame on the saw which was apparently a modification of Hey's saw.

Dr. BIGGER said that saw gave the surgeon the greatest posssible modicum of power that was attainable.

Some of the members having witnessed the working of Dr. Bigger's saws,

The Society adjourned.

Legal Intelligence.

KILKENNY ASSIZES.

PROSECUTION OF A QUACK.

PATRICK HAYNES, aged 85, evidently of the farming class, and who has distinguished himself in the county Kilkenny as a bone-setter, was indicted for having caused the death of Patrick Keys by negligently attending on him and negligently prescribing for him while he (the prisoner) acted in the capacity of surgeon.

It appeared from the evidence that the deceased fell out of a cart and injured his right arm. A day or two after, the arm became inflamed, and he went to the prisoner, who prescribed for him. The accused made some kind of mixture with tar and pitch, placed an iron in the fire, and, when it was heated, drew it through the tar,

He then wrapped a bandage containing the tar tightly around the deceased's arm until it caused him pain. The bandage was left on for several days, until the deceased almost lost the use of his arm, when his wife loosened it. The accused was then informed that Keys was suffering greatly from the plaister, and he ordered it to be taken off and the arm to be then bathed in spring water, and some bandages with cream on them to be wrapped around the arm. The hurt was almost confined to the elbow. Previous to the tar bandage being taken off, his hand became greatly swollen, and his fingers were swollen almost as large as a hand.

Dr. P. Philips deposed that he had held a *post-mortem* examination. Death was caused from mortification. From the wrist up to the shoulder was a mass of mortification, the arm was a black mass of mortified flesh from two inches above the wrist to two inches above the shoulder. The man had died from blood poisoning. Witness was of opinion that the tar over the inflamed part of the arm brought on mortification.

The case for the prisoner was that he had frequently treated in a similar way similar injuries with success, and that the deceased had died from internal hæmorrhage and bad care on the part of his family, his wife having admitted in evidence that she had given the deceased, while he was in fever, two noggins of whisky.

His Lordship, in summing-up, said that the prisoner was in no worse position than if he were a licensed physician in place of a quack on his trial for negligence. The main question for the jury to try was, Was the prisoner possessed of scientific skill which entitled him to have undertaken the charge of such a case, or was it a case of a man undertaking an important function without the slightest knowledge of its duties? The treatment to which Keys was subjected was ridiculously absurd, and they did not require any medical man to tell them that. It was the most dangerous treatment that could be resorted to, and increased the inflammation that had already set in. He hoped that, whatever verdict was returned, the people of Ireland would refrain from having recourse to these quacks. He believed that there was not another country in the world where better ability and skill in medical attendance was obtainable for the people than in Ireland. The poor had the dispensaries, where there were doctors, all over the country, living a life of slavery for a miserable remuneration, and who brought skill and honour to the treatment of each case. Why these people ran after bone-setters was beyond his comprehension.

The jury found the prisoner not guilty.

Dr. Watelet communicates a paper to the *Bull. de Therap.* on this subject: "Accidents following the Administration of Salicylic Acid." The details are given of two cases of rheumatism treated by salicylate of soda, one of which was followed by gangrene of the lower extremities, and both by cystitis, obstinate constipation and coldness of the extremities. In the same journal M. Byasson writes upon "The Action of Salicylic Acid on the Urine." Salicylate of soda, he says, appears in the urine 25 minutes after it has been taken into the stomach, as can be proved by the perchloride of iron test. A dose of 3 grammes is eliminated in between 36 and 40 hours. In its passage through, a portion is eliminated unchanged, the remainder is transformed into salicine, salicyluric acid, and probably oxalic acid. The first urine passed several hours after taking 2 or 3 grammes of salicylate of soda deviates the plane of polarisation to the left; this deviation is due to salicine. Salicylate of soda augments the proportion of the azotised substances and uric acid in the urine.

WEDNESDAY, MARCH 20, 1878.

THE ABUSE OF LIQUID FOOD IN THE TREATMENT OF DISEASE.

There are certain habits which, from long custom, old associations, or preconceived opinion, we find much difficulty in giving up, or the propriety of which we seldom think of questioning. Perhaps the habit of giving liquid food in fevers and other diseases is one of these. In our opinion, it is one of those habits which, notwithstanding it is supported by the prescription of ages, and by many great names, has been greatly abused. How often is the invalid persuaded to take plenty of beef-tea, and other fluid nourishment, in place of more solid and palatable food! How often is solid food withheld from him, under the idea that his stomach cannot digest it, or that it will be rejected, or that it will be too stimulating and productive of pyrexia, or act as an irritant, and give rise to some reflex derangement of the system! There are, however, some signs of this routine practice being partially given up, or at least of its not being resorted to so indiscriminately as in former times. We all know how long it was the custom of the profession to keep the lying-in woman for a whole fortnight upon nothing but gruel and other slops. We now know that this class of patients are allowed a more liberal diet, and that, if all goes on well, there are few accoucheurs who will hesitate to give their patients a chop, or a little boiled mutton, on the third or fourth day. Nor do we ever hear of any inconvenience resulting from this change of practice. On the contrary, the patient's appetite and digestion are thereby improved, she gains strength faster, and her convalescence is much more speedy and pleasurable. Again, very recently, Dr. Turney has even been advocating the use of solid food in typhoid fever; and, although our readers will not be surprised that such

a practice has been severely criticised by Dr. Dyce Duckworth in the columns of the *Practitioner*, we find that in the last number of the same journal, the practice is defended by Dr. Samuel Peters, of Cohoes, N.Y., who states that his experience coincides exactly with that of Dr. Turney. "Over and over again," he says, "I have found that the ingestion of tender meats, or bread and milk, has exercised a beneficial influence on the disease, moderating the diarrhœa, moistening the tongue, restoring consciousness, diminishing heat, &c." He observes that Liebermeister, in Ziemssen's Cyclopædia, argues against the use of proteid compounds in large quantities, but does not condemn them. He also cites one of his own cases—"a type of hundreds that could be cited—" in support of his views. Now, in a question of this kind, we attach very little importance to the opinions of one man, unless they are supported by the experience of many others; still less importance do we attach to one case, or even a dozen cases, but leaving typhoid fever out of the question for the present, there appear to us many reasons which should induce the profession to prescribe solid or semi-solid food more frequently than they are in the habit of doing.

Without appealing to actual experience, we may remark that there are certain physiological considerations which in certain cases should justify our preferring solid to fluid nourishment. Our knowledge of the physiology and pathology of the human frame has made great strides within the last half century, and many practical facts and clinical suggestions are to be found scattered in the pages of the treatises that are devoted to the consideration of those subjects. But we have often thought that our physiological knowledge is not turned to so good an account at the bedside as it might be, and that while we have been burdening the memory with the more minute and theoretical details of that science, we are apt to forget those facts which are more directly applicable to the treatment of disease. With regard to the present question, it should be borne in mind that the fact of certain fluid foods containing a large quantity of "nourishment," of the "real essence" of this or that meat, as people say, is no proof that such food is more capable of fulfilling the object for which it is given, than more solid food would be. The two great factors of digestion and assimilation are to be taken into account. It is generally admitted, that independently of a due adjustment of the albuminous, oleaginous, saccharine, and saline constituents of food, man requires that these constituents should be drawn not from one, but from different kinds of food, and that his diet should be a mixed one, not merely in respect of its proximate constituents, but also in respect of the substances themselves from whence these constituents are derived. Were a man fed long on one particular kind of food his appetite and digestion, and consequently his health, would completely fail from an actual disgust to his monotonous diet, even though it contained a due proportion and quantity of all the constituents above mentioned. There seems to be, therefore, in man a natural craving for a variety in his food, a craving which may even be said to show itself in young children soon after they have begun to cut their first teeth. Now when a patient's diet is for the most part limited to fluids, however rich in nutritious elements they may be, it is impossible to supply such a variety of palatable food as could be done by prescribing more solid nourishment. Consequently the patient takes an aversion to it, an insufficient quantity is taken, and, as if the stomach rebelled against this sameness of food, neither is its digestion or its assimilation so perfect or easy as it should be.
